Abstract. Argumentation represents the study of views and opinions expressed by humans with the goal of reaching a conclusion through logical reasoning. Beginning with the 1950’s, several models were proposed to capture the essence of informal argumentation in different settings. With the emergence of the Web, and then the Semantic Web, this modeling shifted towards ontologies, while from the development perspective, we witnessed an important increase in Web 2.0 human-centered collaborative deliberation tools. Through a review of more than 150 scholarly papers, this article provides a comprehensive and comparative overview of the argumentation domain for the Social Semantic Web. We start from theoretical foundational models and investigate how they have influenced Social Web tools. We also look into Semantic Web argumentation models. Finally we end with Social Web tools for argumentation, including online applications combining Web 2.0 and Semantic Web technologies, following the path to a global World Wide Argument Web.

Keywords: Argumentation, Semantic Web, Social Web, Semantic Web, Ontologies

1. Introduction

In recent years, large-scale argumentation on the Web has attracted the attention of scholars from fields such as artificial intelligence [1], communication theory [2], business management [3] and e-government [4]. At the same time, argumentation researchers began establishing the foundations for a World Wide Argument Web (WWAW) as “a large-scale Web of interconnected arguments posted by individuals to express their opinions in a structured manner” [5].

Arguments on the Web can be used in decision contexts. Decision-making often requires discussion not just of agreement and disagreement, but also the principles, reasons, and explanations driving the choices between particular options. Furthermore, arguments expressed online for one audience may be of interest to other (sometimes far-flung) audiences. And it can be difficult to re-find the crucial turning points of an argumentative discussion in which we have participated. Yet on the Web, we cannot subscribe to arguments or issues, nor can we search for them. Nor can we summarize the rationale behind a group’s decision, even when the discussion took place entirely in public venues such as mailing lists, blogs, IRC channels, and Web forums.

By providing common languages and principles to model and query information on the Web (such as RDF [6], RDFS [7], OWL [8], SPARQL [9], Linked Data principles [10], etc.), the Semantic Web [11] is an appropriate means to represent arguments and argumentation uniformly on the Web, and to enable, for instance, browsing distributed argumentation patterns that appear in various places on the Web. Indeed, researchers have shown that the Semantic Web can be used for visualization and comparison in decision rationale [12].

In this context, this paper discusses argumentation in relation to the Social Semantic Web [13,14,15], focusing on foundational models of argumentation, their applications in the Social Web, and on ontologies (as in Computer Science [16]).

In particular, our purpose is to investigate ontologies and tools which may be useful for argumentation on the Social Semantic Web, a field where the aforementioned Semantic Web technologies support Social Web [17] applications, while at the same time Social Web paradigms are used to generate Semantic Web data collaboratively and at large scale. This convergence aims at providing new and improved ways to
integrate and discover data, following the vision of Social Machines provided by Berners-Lee [18], both on the Web and in the enterprise [19]. In the context of argumentation, this could help to aggregate arguments from various websites — for instance a discussion starting on Twitter and followed up on a mailing list, later frozen on a wiki once consensus is reached — providing new means to follow argumentative discussions on the Web. This would enable an argument-centric view of the Web.

Moreover, the Social Web does not yet have widely-used argumentative ontologies, though this problem has been noted [20], along with the need for federation infrastructures [21]. Thus, in order to identify how different argumentation models and tools can be used for the Social Semantic Web, this paper offers a review of more than 150 research papers on the topic, from 1945 to 2011, from which we compare:

- 13 theoretical models of argumentation
- 14 Semantic Web models for argumentation (i.e. ontologies)
- 37 tools for representing argumentation on the Web.

As the focus is on human-centered argumentation [22], with the goal of improving access and visualization, this article will briefly mention, but not analyze, the agent-based argumentation domain.

Following the introduction, we provide brief overviews of argumentation (Section 2.1) and of the Social Web (Section 2.2), then discuss requirements for supporting argumentation on the Social Semantic Web (Section 3). We next present theoretical models of argumentation (Section 4) from a variety of fields, compare them (Section 5), and present applications of these theoretical models (Section 6). Subsequently we present (Section 7) and compare (Section 8) Semantic Web models of argumentation. Then we move on to reviewing tools: in Section 9 we highlight thirteen noteworthy features of Social Web argumentation tools, based on a comprehensive analysis of thirty-seven relevant tools (see the Appendix for full details). Finally we conclude the paper in Section 10.

2. Background

2.1. Argumentation

Argumentation is the study of agreement, disagreement, and of the dialogues and writing through which we convince ourselves and others of our points of view. Informal argumentation occurs throughout conversations, online and off, often in conjunction with persuasion or with joint decision-making. Social media’s diverse decision-making happens in many online discussion fora such as standardization bodies’ listservs, Wikipedia editors’ wiki pages, and open source communities’ IRC channels, bug reports, and listservs. Even logically sound decisions may involve choices based on values and preference judgments: people may agree on the facts of a situation yet disagree on the preferred outcome or decision to be taken. That is vitally different from disagreeing on the facts of a situation (in which case more information is called for).

There are a variety of common argument structures [23]. A single premise may directly support a conclusion (as in Figure 1(i)), but more commonly, they are combined to come to a conclusion. Premises and conclusions may also be chained (as in Figure 1(iv)).

2.2. Social Semantic Web

The interaction of users around the Web has been shifting from individual siloed Web systems, towards more open and interlinked social applications. In discussion environments, such interlinkage is particularly important: the same community may discuss topics across multiple sites, and use multiple types of sites, such as blogs and microblogs, discussion forums, and wikis. Crosslinking the discussions of these systems is a first step, which has been taken by SIOC – Semantically-Interlinked Online Communities [24]. Yet the internal structure of these discussions – such as whether the participants agree or disagree, are contributing diverse ideas, or debating in circles – is still not represented in SIOC. Capturing such underlying
arguments would be valuable, and research is beginning to address this for instance by identifying argument schemes used in Amazon reviews [25] and by modeling the speech acts in Twitter conversations [26]. Yet infrastructure for argumentation on the Social Semantic Web is still needed.

3. Requirements

What are the requirements for supporting argumentation on the Social Semantic Web? Arguments must be identified, resolved, represented and stored, queried, and presented to users. Identification involves mining arguments, in the form of claims, from text (Section 6.11.2, page 15), eliciting them from users, or some combination of these approaches. Resolving involves indicating the relationships between the individual claims that make up arguments: are they on the same topic? Do they agree or disagree? Representing and Storing arguments uses a suitable ontology to represent claims and the relationships between them. This supports Querying and enables Presenting the Social Semantic Argument Web, i.e. using these ontologies to facilitate access to conversations, summarizing the contentious and agreed-upon points of a discussion.

The representations chosen are key to this process, since they determine what stored information can be retrieved, and what information needs to be mined and resolved. Existing representations will need to be augmented, since the information we can retrieve depends on what information we store. The desired ontologies should encompass not only the structural features of posts (such as the date and author of a post) and of conversations (such as the reply structure of multiple posts), but also additional argumentative features, for instance to mark claims and to indicate the relationships between them. The simplest relationships for representing argumentation indicate whether pairs of claims support or challenge each other. Yet in general, these relationships do not just pertain to pairs: in general, entire groups of arguments may need to be considered together.

Even simple scenarios may give rise to complex argumentation involving chains of statements, and context-dependent relationships in which the conclusion of one argument is premise of another [27]: this makes the graph structures of the Semantic Web a natural fit. Wyner et al. suggest that besides agreement and disagreement, the semantic types of arguments should at least include introduction of a premise or exception, refinement, and pronominal anaphora and call for a modular architecture “where different relationships or debate components may be added systematically” [27].

3.1. Example Applications & Requirements

We envision two main approaches to argumentation on the Social Semantic Web:

1. Focusing on the real-time, dialogical nature of the Social Web, i.e. by soliciting arguments from humans through conversation and real-time exchange.
2. Focusing on the Social Web as a source of artifacts, i.e. by using existing natural language conversations and reconfiguring the traces and archives of these conversations.

Examples of the first case would be a chatbot or an interactive webform; these could help populate a knowledge base or enable argumentative interaction between humans and intelligent agents. Examples of the second case would be summaries or interactive conversation browsers; a discussion summary could highlight the agreement and disagreement about a topic expressed in a number of Social Web sources, or a review browser could enable faceted navigation through reviews based on the factors they mention, and the polarity and strength of the reviewer’s perspective on each such factor.

Formal semantics will be needed in both cases, but for different functions. In the first case, formal semantics translate from natural language to agent-appropriate vocabularies, potentially enabling reasoning over human input. Argumentation has long been used for planning between agents, and agent-based approaches to the Semantic Web are common [28], and there has been some work in mediating between humans and agents [29,30]. In the second case, the semantics will mainly be useful for presenting humans with visualizations, therefore the ease of mining and presenting representations, and the suitability for human understanding, should be preferred.

Another factor is how—by what process and agent—arguments are translated into the formal semantics. This may be the responsibility of a human or machine. If argumentation is annotated by humans—either the person posting a comment or other individuals—they will need sufficient understanding of the model as well as a suitable incentive or motivation for annotating. Algorithmic annotation is limited by our current
understanding of informal argumentation, and by the multilayered meaning of conversations. For work with traces, annotation after the fact will be more common, yet lossy: non-participants and machines may be limited by lack of awareness of the context and of subtle language cues.

Models supporting human navigation (e.g. to support our second example above) should make psychological sense; this is not a factor for internal representations for machines. In either case, to ensure feasibility (for either human or algorithmic entry), argumentation classifications need to be clearcut. Thus, the granularity of the model must be limited.

4. Theoretical Models of Argumentation

This section discusses thirteen theoretical models for capturing argument structure: Toulmin [31], Issue-Based Information Systems [32], Walton [33], Dung’s Argumentation Frameworks [34], Value-based Argumentation Frameworks [35], Speech Act Theory [36], Language/Action Perspective [37], Pragma-dialectic [38], Metadiscourse and Structural Elements of Text [39], Rhetorical Structure Theory [40], Coherence [41], and Cognitive Coherence Relations [42].

4.1. Toulmin

Informal argumentation originated in philosophy, with Toulmin’s 1958 account of informal argumentation [31]. Toulmin sought to find a common underlying basis for arguments in every field of human activity. His model applies, for instance, to legal, scientific, and informal conversational arguments. In Toulmin’s theory, evidence and rules called Warrants support Claims. Claims may also be qualified (i.e. with constraints or to indicate uncertainty); Rebuttals may be used to argue against an argument. Toulmin’s argument pattern is shown in Figure 2: Data is supported by Warrants which have Backings, showing that a Claim holds with Qualifiers regarding the situation, unless there is a Rebuttal. Figure 3 shows Toulmin’s now-famous argument, presented according to this structure.

4.2. Issue-Based Information System (IBIS)

IBIS, Issue-Based Information System, is a problemsolving structure first published in 1970 [32]. As the name suggests, IBIS centers around controversial issues which take the form of questions. Specialists from different fields may use the same words with different assumptions and intentions, hampering communication. IBIS is especially intended to support community and political decision-making. In this scenario, there may be three separate groups—the participants in the discussion, the relevant experts, and the decision makers—each of whom need to communicate with each other and who must also get information from existing records and documentation.

IBIS, as originally designed, is a documentation system, meant to organize discussion and allow subsequent understanding of the decision taken; this explains the use of “Information System” in its acronym. The context of the discussion is a discourse about a topic. Issues may bring up questions of fact and be discussed in arguments. Here, “Arguments are constructed in defense of or against the different positions until the issue is settled by convincing the opponents or decided by a formal decision procedure,” [32]. IBIS also recognizes model problems, such as cost-benefit models, that deal with whole classes of problems.

2“Many central terms used are proper names for long stories specific of the particular situation, with their meaning depending very sensitively on the context in which they are used.” [32]
Several kinds of relationships exist between issues: direct successor, generalization, relevant analogy, compatible, consistent, or inconsistent. The method also distinguishes issue content, as factual, deontic (“Shall X become the case?”), explanatory, or instrumental (“Shall we take approach X to accomplish Y?”).

Originally implemented as a paper-based system, IBIS influenced several ontologies and numerous tools (see Section 6.2, page 10) as well as procedures such as dialogue mapping [44].

4.3. Walton

The Canadian philosopher Walton has written extensively on argumentation for more than thirty years (e.g. [45,46,47]); a 2010 festschrift honoring his contributions [48] shows how his work has influenced and been applied to computer argumentation. Informal argumentation is one of Walton’s specialties [49]. His seven types of dialogue are shown in Figure 4 on the next page. These types are Persuasion, Inquiry, Discovery, Negotiation, Information-Seeking, Deliberation, and Eristic. They are distinguished by the initial situation, the individual goals of the participants, and the overall goal of the dialogue. In our own view, these types of dialogue can be classified based on whether knowledge plays a large, middling, or minor role. Inquiry, Discovery, and Information-seeking dialogues are almost entirely knowledge-based, while knowledge plays only a minor role in Negotiation (aiming at a harmonious settlement) and Eristic (quarrels, beneficial mainly for venting emotions). Knowledge plays some role in the remaining two types: in Persuasion and Deliberation, opinion and belief also have a large role.

According to Rahwan [23], while many taxonomies of argumentation have been proposed [52,53,54,55], Walton’s taxonomy [56] provides the point of departure for computational models of argumentation. In his detailed classification from 1995 [56], Walton describes each scheme with a name, a conclusion, a set of premises, and a set of critical questions. Critical questions address the points where this argument scheme may break down, and suggest attacks against the argument. For example, the following six critical questions are associated with the Argument from Expert Opinion [57]:

1. How credible is E as an expert source?
2. Is E an expert in the field that A is in?
3. Does E’s testimony imply A?
4. Is E reliable?
5. Is A consistent with the testimony of other experts?
6. Is A supported by evidence?

Walton’s 2008 book [33], coauthored with computational argumentation researchers, presents 65 general argumentation schemes, presumably updating [56]. Further complexity arises because dialogue types may shift in an actual discussion, and argument schemes may be embedded in one another [51].

4.4. Dung’s Argumentation Frameworks

Dung provides a powerful graphical model of argumentation frameworks in [34], which has been widely used in computational argumentation. Argumentation frameworks are defined as sets of arguments and attacks between them. Formally, an argumentation framework is a pair $AF = (AR, attacks)$ where $AR$ is a set of arguments, and attacks is a binary relation on $AR$, i.e. $attacks \subseteq AR \times AR$.

![Fig. 5. Example of an argumentation framework](image)

Then the questions of interest are to find maximal sets of arguments that do not attack each other (these

---

3Walton’s taxonomy has been revised several times. ‘Discovery’ was not in several earlier formulations, such as [46], page 183; it is motivated by choosing the best hypothesis for testing. Debate and Pedagogical appeared in an earlier formulation [50] which provides descriptions of the goals of each dialogue.

are called conflict-free), and to find arguments that are not defeated by a given set of arguments (these are called acceptable). A conflict-free set of arguments is then considered to be admissible if each argument is acceptable with respect to the set.

Dung then finds maximal admissible sets, known as preferred extensions.

A simple argumentation framework is shown in Figure 5 on the preceding page. In this example, A and B attack each other; A also attacks C; and D is not attacked. Thus A,D and B,C,D are preferred extensions.

4.5. Value-based Argumentation Frameworks

Value-based Argumentation Frameworks [35], based on Dung’s argumentation frameworks, address persuasion. It is not just differences about the facts, or failures in logic that can cause reasonable people to disagree: differences in values can also be to blame. In practical reasoning, two people can come to different, consistently logical opinions, based on a difference of values: “A key element in persuasion is identifying the value conflict at the root of the disagreement so that preference between values can explicitly inform the acceptance or rejection of the competing arguments.” The theory of Value-based Argumentation Frameworks thus draws from Perelman’s notion of audience [52]: arguments are often addressed to particular audiences, and persuasive arguments are those aligned with the audience’s values and preferences. Value-based Argumentation Frameworks provide a method for logically calculating consistent approaches, distinguishing between the facts of a situation and community members’ values.

4.6. Factor Analysis

There is a large business market in legal information retrieval, and one method for classifying and indexing legal cases has been the key dimensions or factors which “capture the legal relevance of a cluster of facts to the merits of a claim” [58]. Factors such as “Obligation to aid the victim” or “Failure to heed traffic signs” contribute to determinations of culpability, and have been recorded in manually constructed databases [58]. Factor analysis can be helpful in supporting community decision-making or in summarizing reviews.

4.7. Speech Act Theory

Searle’s Speech Act Theory [36] describes five categories of speech acts: assertives, directives, commissives, expressives, and declaratives. Speech acts are about the force of a statement: what effect they seek to have on the hearer or the world. Assertives (“The sky is blue”) assert that something is true. Directives (“Clean your room”) order, permit, or request something. Commissives are vows or pledges (“I swear to

tell the truth’). Expressives offer thanks or congratulations, or express feelings (‘Great work!’). Declarations (‘I now pronounce you man and wife’) enact what they say, effectively changing reality.\(^5\) Several approaches to conversation and argumentation have been derived from speech act theory.

4.8. Language/Action Perspective

The Language/Action Perspective (LAP) [37] embeds Speech Act Theory in a task-based framework. Argumentation is found in each of the three types of conversations which accomplish goals in the Language/Action Perspective, according to de Moor and Aakhus: Conversations for action involve making commitments; conversations for possibility create a context for action; and conversations for disclosure allow participants to share their views and concerns [59].

4.9. Pragma-dialectic

The pragma-dialectic approach is a complete argumentative theory, which has been developed over a number of years in numerous scholarly works (especially [60,54,38]) and popularized in the authors’ textbooks (e.g. [61]). Like the Language/Action Perspective, it uses speech acts, further developing Searle’s theory in order to model argumentation. Rather than focusing on the logical forms and patterns of reasoning, as Walton does, van Eemeren and Grootendorst’s pragma-dialectic theory views argumentation as a social process, used to settle “a difference of opinion by verbal means” [61], pp. ix-xii.

Depending on the context, the same speech acts can function as an explanation, a piece of information, or as an argumentation: for argumentation, the context must include a difference of opinion. Depending on their order and position in the discussion, speech acts take on different meanings, as we will see in Figure 6. Further, Searle’s illocutionary speech acts, which function at the sentence-level, combine in argumentation into a higher-order textual element: the argumentation is itself seen as a complex speech act.

The main speech acts within an argumentation are assertives, commissives, and directives. Expressives—which express emotions—do not help resolve the difference of opinion, but may affect how or whether the discussion proceeds. Declaratives—which bring a state of

\(^5\)As with all speech acts, sincerity is a criterion, and social criteria, e.g. ceremony, may also hold.

Fig. 6. Distribution of speech acts in a critical distribution from [38].

affairs into being—re relevant for definitions, specifications, amplifications, and explanations; van Eemeren and Grootendorst call these “usage declaratives”.

The pragma-dialectic approach also stresses the principles of clarity, honesty, efficiency, and relevance, updating Grice’s [62] Cooperation Principle—which focuses on the intention of language—with the Searlean focus on the communicative aspects of language use. Relevance, for example, can be global, local, subject matter-specific, or probative. An argument may be relevant at one phase, but irrelevant at another point; for example an argument related to selecting the topic of discussion is not relevant once the topic has been agreed upon.

To understand the force of a speech act—whether an assertive, commissive, or directive—, we must identify where we are in the argumentation. van Eemeren and Grootendorst identify four dialectical stages of argumentation: Confrontation, Opening, Argumentation, and Closing [38]. In the confrontation stage, the issue at hand is announced, agreed upon, or clarified. In the opening stages, the rules are agreed to (perhaps implicitly). In the main stage (Argumentation), each party is expected to make a serious effort to support his point of view, while also allowing the other party to make his case. Finally, the argument closes when the goal is fulfilled or the parties agree to end the debate.
The pragma-dialectic approach is far more extensive in attending not only to linguistic patterns, but also to the social context in which they are embedded (i.e. the linguistic pragmatics, see e.g. [63]). Argumentative discourse starts with the assumption that the listener does not (necessarily) agree with the speaker’s position, and aims at “coming to a reasonable agreement” [61], p 4. Speakers may anticipate objections, explaining their reasoning to account for expected (implicit) differences of opinion. Or, they may wait to hear their conversational partners’ standpoints or doubts, and then respond with explanations.

The issue, according to the pragma-dialectic theory, may be single or multiple, and mixed or non-mixed. Single disagreement is about just one proposition while multiple disagreement is about more than one proposition. If both a positive and a negative standpoint are taken on the issue, the disagreement is mixed, otherwise it is simple. This is a particularly useful distinction for conversations in social media.

Pragma-dialectic is also particularly useful for determining which parts of social media discourse can be considered argumentative, since it presents phrases that tend to mark argumentation, and since it treats speech acts from an argumentative perspective. For example, doubt is often implicit, but certain phrases mark it more explicitly, such as “I don’t know whether”, “I’m not yet convinced that”, “ Couldn’t it be that”, and “I’ll have to think about whether”.

Similarly, set phrases often indicate the topics of a debate—helping us detect a participant’s standpoint, which “expresses a certain positive or negative position with respect to a proposition” [38] p3. Standpoints may often be obliquely stated, yet they can sometimes be recognized by the appearance of particular phrases, which can be baldly stated (“my standpoint is that”, “we are of the opinion that”) or explicit (“I think that”, “if you ask me”, “therefore”). Some phrases that may be used to indicate a standpoint also permit alternate interpretations (“the way I see it”, “in other words”, “all things considered”). Other patterns, like “shouldn’t”, “you must never”, “that...is”, “ought to be”, commonly co-occur when a standpoint is expressed. [61], pp. 10-12.

Such phrases, like the metadiscourse markers we discuss next, can potentially be applied in argumentation mining (which we later discuss in Section 6.11.2, page 15), but this utility is tempered by the need for context for properly reconstructing argumentation: “In language use there is often the case that there is more than one purpose at the same time, and if language is used argumentatively, the argumentative function need not always be the most important,” [38] p23, meaning that reconstructing argumentation must extract a single thread of meaning out of many.

4.10. Metadiscourse and Structural Elements of Text

Metadiscourse refers to the “aspects of a text which explicitly organize a discourse or the writer’s stance towards either its content or the reader.” [39](page 14). Argumentative phrases such as ‘but’ and ‘according to X’ are prominent examples. Metadiscourse is used not only to structure text but also to influence the reader’s view.

Hyland classifies metadiscourse into interactive and interactional types. Interactive metadiscourse, which organizes text, includes transitions (in addition, but, thus, and); frame markers (finally, to conclude, my purpose is); endorphoric markers (noted above, see Fig. in section 2); evidentials (according to X, Z states); and code glosses (namely, e.g., such as, in other words) [39](page 49). Interactive metadiscourse, which makes the author’s views explicit and invites readers’ response, includes hedges (might, perhaps, possible, about); boosters (in fact, definitely, it is clear that); attitude markers (unfortunately, I agree, surprisingly); self mentions (I, we, my, me, our); and engagement markers (consider, note, you can see that).

As markers of the persuasive and rhetorical elements of texts, metadiscourse elements are likely to be useful signals for identifying claims arguments in social media.

4.11. Rhetorical Structure Theory

Rhetorical Structure Theory (RST) [40], a method for analyzing texts according to their structure and rhetorical role, was developed at the University of Southern California’s Information Sciences Institute to assist with computer-based text generation. In RST, structures such as ‘Concession’, ‘Evidence’, and ‘Justify’, called ‘relations’, describe the relationship of two or more spans of text. Generally one span (the most important) is called the nucleus, while the less important spans are known as satellites. In some situations (such as sequences and contrasts), both spans are nuclei of equal weight. Justifications and hedges are more likely to appear in satellites while the nucleus is more likely to contain claims; this has potential application in detecting arguments and in summarizing social web applications.
4.12. Coherence

A more general (though less actionable) approach is to consider coherence, which is both an essential part of text, and an essential part of argumentation. Knott compares the following two examples [41].

1. “Tim must love that Belgian beer. The crate in the hall is already half empty.”
2. “Tim must love that Belgian beer. He’s six foot tall.”

While the first example is coherent the second example is more challenging to make sense of: the reader expects (but does not get) a sensible explanation or evidence for why Tim must love that Belgian beer.

Argumentation relies on coherence: Adding ‘because’ works in the first example but not in the second example. The word ‘because’ stresses the expected causal relationship, making the informal argument more evident.

3. “Tim must love that Belgian beer, because the crate in the hall is already half empty.”

In Sentence 3, the reader must still infer some information, such as that the crate in the hall contains Belgian beer, and that Tim is the main person drinking the contents of the crate. Such missing premises are typical in informal argumentation.

4.13. Cognitive Coherence Relations

One actionable way of expressing coherence is by using specific signaling terms. The causal relationship (expressed in ‘because’) is one of the Cognitive Coherence Relations which Sanders uses to explain how readers understand text [42]. The four Cognitive Coherence Relations are: Basic Operation (causal or additive), Source of Coherence (semantic or pragmatic), Polarity (positive or negative), Order of Segments (for causal relations only: basic or non-basic, depending on whether or not the antecedent appears before the consequent). Based on this, the relationship signaled in because in Sentence 3 (above) is causal, pragmatic, positive, and basic.

5. Comparison of Theoretical Models

Any of these models could be expressed in semantic formats (e.g. RDF) since they are compatible with a graph-based representation of argumentation. Yet for modeling argumentation on the Social Semantic Web, it is most meaningful to examine the challenges and opportunities that might advantage any one model or framework over the others.

We can make several distinctions between models, for instance based on the community in which they originated, their purpose or use, the extent to which they focus on disagreement, the unit of analysis on which they focus, their granularity, and their suitability for automation or for aiding human reasoning.

5.1. Community of Origin

Various communities have contributed models, particularly the argumentation and linguistics communities. The IBIS model comes from management and was later taken up by design rationale and human-computer interaction (HCI) communities. The Language/Action Perspective originated in artificial intelligence and HCI and was later adopted by communication theorists. In some cases, models bridge communities: the pragma-dialectic approach is an argumentation model which has been heavily influenced by linguistics, and of the theory of pragmatics [63] in particular. Models have been shaped by their originators and proponents, and the purposes for which they were intended.

5.2. Purpose or Use

The intended purpose for models depends largely on their origin. Models put forth by the argumentation community are generally designed to support either analysis (e.g. to determine the reasoning patterns used and to identify fallacies) or formal reasoning, in order to address questions such as computational decisions of which argument won, what the deciding factors were, or what values and preferences were expressed in the discussion. Models of linguistic features may be used in discourse analysis, for summarization, and to support natural language generation by both machines and non-native speakers. Models from other communities are generally intended to support flow-based process analysis, for instance to organize information in order to avoid information overload, to speed human decision-making, and to provide a record of collaborative thought processes.

5.3. Agreement/Disagreement Focus

Disagreement and the process of coming to consensus are the core of argumentation. While disagree-
ment and agreement are central in models coming from the argumentation community, other models focus on this core to a greater or lesser extent. Most linguistic models are considerably broader and less focused on the argumentation aspects, yet in addressing conversation, they provide valuable insights as well as analysis tools. HCI models focus on supporting collaboration and shared visions; disagreement is analyzed or understood only to the extent necessary for coming to consensus or visualizing viewpoints.

5.4. Unit of Analysis

Different units of analysis have been used. At the language layer, models may focus on the relationship between different clauses (Metadiscourse, Coherence, Cognitive Coherence, RST) or the communicative function of different words, phrases, and sentences (Speech Act Theory and the Language/Action Perspective). The pragma-dialectic approach focuses on the propositional level, while factors analysis looks at important attributes or dimensions. Other models focus on classifying individual arguments and their relation to a whole (IBIS), or studying the internal structure of arguments (Toulmin, Walton, Argumentation Frameworks, Value-based Argumentation Frameworks).

5.5. Granularity

Models of linguistic features are more granular, but sometimes less focused on the overall structure. Coarse-grained and simple models, such as IBIS, more common in application. Yet even IBIS is not generally applied in its full complexity, but is rather reduced to focusing identifying issues, and then on identifying pros and cons for a particular issue. Fuller versions become more complex by looking at the relationships between arguments: what responds to what.

5.6. Ease of Application

Mechanistic application is possible for some models but not for others. In particular, classification for Walton’s model would be quite difficult due to the large number of argument categories and the need for detailed reasoning. On the hand, in many cases language technologies can be mechanically analyzed. Identification and classification of argumentation via language technologies is still in its infancy, yet offers great potential to expand algorithmic understanding of language.

5.7. Support for Human Reasoning

To aid human reasoning, however, linguistic models that mainly use cue words are probably too granular since they occur at the sentence level, probably more granular than needed. For this purpose, Walton’s critical questions are very useful, because they can point humans to the questions that need to be addressed, opening the door to checklists for reasoning, which could be applied consistently by groups. Value-based frameworks also address the basic reasoning underlying social decisions: each person has their own reasons, which get indicated in discussion. Focusing on what the values are, and being able to articulate them, can help both in developing empathy for dissenting viewpoints, and in making clear the rationale for group decisions when consensus is needed.

6. Applications of the Models to the Social and Semantic Web

The theoretical models discussed have been quite influential, and in many cases we can directly trace Social and Semantic Web applications of these models. In this section we describing some applications, reviewing each of the models in turn.

6.1. Applications of Toulmin

Toulmin is cited frequently and in numerous fields, from rhetoric (e.g. [64]) to education (e.g. [65]) to computer argumentation (e.g. [66]). While his model is a useful abstraction, scholars have argued about whether people actually think in terms of Toulmin’s warrants [67]. One early hypertext system, SEPIA, drew from the Toulmin system [68]. In the Semantic Web, the Toulmin Argument Model is implemented by an OWL 2 DL ontology that imports CiTO\textsuperscript{6} [69]. It follows Toulmin’s model closely, as shown in Figure 7 on the facing page.

6.2. Applications of Issue-Based Information System (IBIS)

Although many tools are described as ‘using the IBIS model’ or ‘IBIS-like’, there is significant variation in the underlying structure of these models [70].

\textsuperscript{6}http://www.essepuntato.it/2011/02/argumentmodel
In our view, these models use ‘IBIS-like’ to mean that they concern decision-making or design rationale, provide graphical representations, and use some form of polarity.

The IBIS model has a long history of use, particularly with early hypertext systems. Early critiques of IBIS came from the design rationale community. One difficulty was that only deliberated issues were included; Procedural Hierarchy of Issues (PHI) modifies IBIS to allow inclusion of subissues which are not deliberated [71]. PHI was adopted by another early system, the Author’s Argumentation Assistant [72], which also drew from the authors’ earlier Toulmin-based system, SEPIA [68].

Another difficulty, representing the relationships and interdependencies of issues [71], remains challenging to resolve, though ideas such as nonfunctional requirements and dependencies (Section 7.6, page 19), might be relevant.

IBIS has also been used outside of design rationale. For instance, Gerosa et al. [73] discuss an e-learning message board system adopting a modification of IBIS, where message types are specified. In addition to the IBIS-analogues, Question, Argumentation, and Counter-Argumentation, the system adds two types: Seminar (a general topic for the week) and Clarification. IBIS has also influenced the design of modern ontologies, including the SALT Rhetorical Ontology, SIOC-Argumentation, DILIGENT, and the Change Ontology which we discuss after reviewing IBIS’ RDF representation.

6.2.1. IBIS RDF
IBIS RDF\(^7\) is an RDF representation of the IBIS model. refersTo is modelled as a subProperty of dcterms:reference with two subproperties, pro and con. The larger IBIS vocabulary provides Published Subject Indicators\(^8\) for important terms, including pro, con, Idea, Question, Argument, Decision, and Reference.

6.2.2. SALT Rhetorical Ontology
SALT [74] is a rhetorical ontology for scholarly communication. In SALT, opposing arguments can be connected together with the relation hasCounterArgument, while a RhetoricalElement can also be connected with what it argues for (Argument and hasArgument, for instance). SALT’s argumentation also includes Reason, which contains Argument (further specified to PositiveArgument or NegativeArgument) and CounterArgument.

6.2.3. DILIGENT ontology
DILIGENT provides an argumentative structure for collaborative ontology construction; the acronym comes from the phrase DIstributed, Loosely-controlled and evolvInG Engineering processes of oNTologies. DILIGENT draws from both RST (Section 4.11, page 8) and IBIS (Section 4.2, page 4), as shown in Figure 8 on the next page.

6.2.4. Change Ontology (ChAO) in Collaborative Protégé
DILIGENT [76] itself influenced The Change Ontology in Collaborative Protégé. Castro et al. distinguish between an argument (which is well-focused and specific) and an elaboration (which provides support for the argument, possibly with file attachments) [76]. Positions become clear through the dispute-resolution process. With Protégé, various argumentation-related Annotations can be added, including Explanation, Proposal, and AgreeDisagreeVote [77].

6.2.5. SIOC-Argumentation
The SIOC-Argumentation\(^9\) model [78] expands on the IBIS model with terms such as Decision and Argument. It is provided as an extension of SIOC — Semantically-Interlinked Online Communities [24] — a model that focuses on representing online communities and the content shared within them.

---

\(^7\)http://purl.org/ibis
\(^8\)http://www.topicmaps.org/xtm/index.html#def-published-subject-indicator
\(^9\)http://rdfs.org/sioc/argument
While SIOC simply focuses on the notion of replies (sioc:reply_to) to represent connections between discussion items, the SIOC-Argumentation module goes further and provides finer-grained representation of discussions and argumentations in online communities.

So far a modification of SIOC that draws from DILIGENT and OMDoc has been used in the math wiki system SWiM\textsuperscript{10} [79], a Semantic Wiki for Mathematical Knowledge Management. The SIOC/OMDoc argumentation ontology (Figure 9 on the facing page) is further described in Lange’s dissertation [80]. It incorporates IBIS-style classes from SIOC (Position, Decision, Idea, and Issue), as well as domain-specific argumentation classes for math (e.g. Wrong, Keep_as_Bad_Example, Incomprehensible).

As opposed to IBIS-RDF, SIOC-Argumentation (Figure 10 on the next page) provide the means to easily integrate argumentation modelling patterns with Social Web applications since it relies on SIOC, already used in various applications (Drupal7, etc.). However, SIOC-Argumentation has limitations: it does not represent taxonomic, causal, or similarity relations, which prevents its use in contexts such as full-on argument analysis.

6.2.6. SWAN-SIOC

SWAN-SIOC [81] harmonizes the argumentation aspects of two pre-existing ontologies: along with SIOC, it is based on SWAN — Semantic Web Applications in Neuromedicine [82] — an ontology which focuses on scientific communication in neurology.

SWAN/SIOC uses twelve terms, as shown in Figure 11 on the facing page. The most general term is relatedTo, which has five direct descendents or subterms. These, in turn, may have subterms, until we reach the base terms in the ontology: disagreesWith, agreesWith, and discusses. SWAN/SIOC provides a simple model for the relationships between items. Tools using SWAN-SIOC include POnline, which is discussed in Section A.33, page 44.

6.3. Applications of Walton

Walton’s model has been widely applied in computational argumentation [48], and a recent paper suggested demonstrated how argument schemes could be used to aid sensemaking in Amazon reviews [25]. Avicenna and ArgDF incorporate Walton’s schemes. The only Social Web application we are aware of is Parmenides\textsuperscript{11} [84,85,86], which uses the following argumentation scheme and value-based argumentation frameworks:

**Argumentation Scheme AS1:**

\textsuperscript{10}http://kwarc.info/projects/swim/demo.html

\textsuperscript{11}http://cgi.csc.liv.ac.uk/~parmenides/
Fig. 9. The argumentation ontology from SWiM extends SIOC-Argumentation and DILIGENT Argumentation [79].

Fig. 10. An overview of the SIOC-Argumentation module from [78].

Fig. 11. fWAN-SIOC ontology from [83].
In the current circumstances $R$, we should perform action $A$, to achieve new circumstances $S$, which will realize some goal $G$, which will promote some value $V$.

The following sixteen critical questions are associated with Argumentation Scheme AS1:

CQ1 Are the believed circumstances true?
CQ2 Assuming the circumstances, does the action have the stated consequences?
CQ3 Assuming the circumstances and that the action has the stated consequences, will the action bring about the desired goal?
CQ4 Does the goal realize the value stated?
CQ5 Are there alternative ways of realizing the same consequences?
CQ6 Are there alternative ways of realizing the same goal?
CQ7 Are there alternative ways of promoting the same value?
CQ8 Does doing the action have a side effect which demotes the value?
CQ9 Does doing the action have a side effect which demotes some other value?
CQ10 Does doing the action promote some other value?
CQ11 Does doing the action preclude some other action which would promote some other value?
CQ12 Are the circumstances as described possible?
CQ13 Is the action possible?
CQ14 Are the consequences as described possible?
CQ15 Can the desired goal be realized?
CQ16 Is the value indeed a legitimate value?

6.4. Dung’s Argumentation Frameworks

Dung’s argumentation frameworks has been incredibly influential: as of 2011, the original 1995 paper has over 450 citations in the ACM Digital Library, and over 1500 in Google Scholar. This approach has driven computational research in argumentation and provided the basis for a large body of theoretical work. Among theoretical extensions of Dung’s work, we have focused on Value-based Argumentation Frameworks, and the relevant Social Web application of Dung is in fact an application of that extension, as we next explain.

6.5. Applications of Value-based Argumentation Frameworks

Parmenides uses value-based argumentation frameworks in addition to the argument scheme and critical questions discussed above. It pinpoints the source of the disagreement, by having participants respond to a series of questions in a survey format. The group’s preferences are revealed in the results, which are displayed in graphical argumentation frameworks.

6.6. Applications of Factor Analysis

Factor analysis has been applied in Ashley’s legal argumentation systems, but we know of no specific Social Web applications.

This approach is still used by commercial providers of legal information [87]. More recently, automatic text mining has been used to identify these factors [87]. Generalizing factors, perhaps using argument schemes and critical questions, could provide another approach to argument mining; see for instance Heras’ manual application of argument schemes to Amazon reviews [25].

6.7. Applications of Speech Act Theory

In the Semantic Web context, where assertions can be modelled using RDF, Carroll et al. [88] use the idea of performative warrants, to describe assertions made legitimately by the authority signing a Named Graph. Speech acts are also used to model the flow of online conversation in several recent works. Jeong et al. [89] use semi-supervised machine learning to identify speech acts in email and forum posts. Ritter et al. [26] model Twitter conversations with Speech Act Theory in combination with topic modelling and show a Speech Act transition map with probabilities for each state.

6.8. Applications of the Language/Action Perspective

Using the Language/Action Perspective and drawing from Speech Act Theory, Twitchell et al. [90] model online conversations to classify them and create visual maps, used for information retrieval:

“Using current search engines, the searcher could search for the words Vietnam, war, and critique. However, many critiques of the war might not contain the word critique, and would thus be lost (or
receive a low ranking) in such a search. **If the searcher was able to issue a query such as Vietnam war (critique) where critique is the purpose of at least one participant in the conversation, she would likely get better results.** The search for the semantic meaning of the words Vietnam war using conventional searching techniques would then be combined with the search for the pragmatic force of the word critique, yielding a search result with higher precision than searching on semantic meaning alone.” [90]{bold, underline added}.

Attending to Speech Acts can also help predict deception, which uses ‘fewer assertions and more expressives’ [90].

### 6.9. Applications of Pragma-dialectics

We are not aware of any argumentation tools specific to pragma-dialectics. de Moor, however, has taken a reconstructive approach to argumentation based on pragma-dialectics (e.g. [59]).

Pragma-dialectics has also been very influential in the argumentation community, integrated into e.g. Walton’s textbook descriptions of argumentation [49] and discussed in at least one journal special issue [91] and edited collection [92].

### 6.10. Applications of Metadiscourse and Structural Elements of Text

Parsing argumentation from natural language often takes advantage of metadiscourse and document structure. Two particularly promising approaches come from Teufel and Sándor. Teufel’s rhetorical component extraction uses machine learning to extract and classify text according to its rhetorical status [93]. Sándor’s concept-matching framework detects contrasting ideas linguistically, using metadiscourse and rhetorical markers [94]. Rather than determining the relations between text spans, Sándor uses her concept-matching framework to infer contrasts, novel information, etc. from the author’s metadiscourse [94].

Teufel and Moens focus on the document-level context, rather than the relationship between text spans. In their argument zoning, machine learning is used to extract and classify text from academic articles according to its rhetorical status [93]. Sándor and Teufel and Moens provide contributions in risk assessment, annotation, and audience- and task-specific summarization. Reuse of their work has included an application to find rhetorical features of related work sections, first using classification algorithms, and then applying ontologies [95]. However, these techniques are of particular interest here because of further work in argument mining drawing on these ideas, which we soon discuss (Section 6.11.2, page 15).

### 6.11. Applications of Rhetorical Structure Theory

RST has been widely used for a variety of purposes—sand in 2006 a paper summarizing its applications [96] was published. Recently, Mentis et al. [97] used RST to analyze group decision rationale, comparing new and established groups using relations such as ‘Interpretation & Evaluation’, ‘Evidence’, ‘Elaboration’, ‘Concession’, and ‘Antithesis’. Summarization research has frequently drawn upon RST [98,99].

#### 6.11.1. DILIGENT

DILIGENT, briefly discussed above as an application of IBIS (Section 4.2, page 4), also draws from RST (Section 4.11, page 8) as shown in Figure 8 on page 12. To improve the agreement, clarity, and satisfaction [75] of discussions for ontology creation and refinement, DILIGENT restricts the argumentation. Five argumentative relations — alternative, evaluation and justification, counterExample, elaboration, and example — were drawn from RST [79], based on the arguments that advanced the ontology creation process in an experiment [100].

#### 6.11.2. Argumentation Mining

Drawing from rhetorical parsing, argument mining is a new area of study which seeks to detect and extract arguments from texts algorithmically. Mochales-Paulau’s current dissertation work focuses on mining arguments [101,102,87] from the European Court of Human Rights and from the Araucaria annotated corpus [103], based on Context Free Grammars [87] as well as techniques from Teufel and Moens. Earlier Grover et al. [104] adapted Teufel and Moens’ approach to determine the argumentative role of sentences drawn from a corpus of legal judgments.

In “Automatic Argumentation Detection and its Role in Law and the Semantic Web” [101], Mochales-Paulau and Moens suggest that argument mining could contribute to the World Wide Argument Web [5], by
extracting argument structures without human annotation. As they point out, automatic argument detection is needed at multiple levels: the inner structure of each argument as well as the overall structure of how multiple arguments are combined to contribute to the argumentative discourse.

6.12. Applications of Coherence

We are not aware of direct applications of the theory of coherence, perhaps because it is insufficiently operationalized to suit an actionable implementation. At least one specific theory it influenced—that of cognitive coherence relations, which we discuss next—has been influential.

6.13. Applications of Cognitive Coherence Relations

Cognitive Coherence Relations contributed to the development of ScholOnto [105]. In separate work, Mancini’s cinematic hypertext [106] used Cognitive Coherence Relations to develop a visual language for structuring hypertext links, increasing the coherence of argumentation conveyed in non-linear hypertext by clearly expressing the rhetorical relationships between chunks of text. Meanwhile, agent-based argumentation has used Cognitive Coherence Relations as a theory of pragmatics [107].

The ScholOnto [108,109] project, which ran at Open University’s Knowledge Media Institute from 2001-2004, focused on modeling claims and arguments in scholarly communication. ClaiMapper, ClaiMaker, and ClaimSpotter were among the tools developed in the project, which was seen as part of sense-making research. An open source web publishing tool called the Digital Document Discourse Environment [110] was also developed in related research. ScholOnto made an RDF Schema available, but database queries with SQL were preferred to querying based on this RDF Schema (SPARQL was first released as a working draft in 2004). The underlying ScholOnto ontology for these projects is shown in Figure 6.13 on the facing page. This ontology now underlies Cohere, argument mapping software for sense-making that integrates annotation and argumentation for the general public [111].

7. Ontologies incorporating argumentation

In addition to the seven ontologies discussed above, which implement or follow from particular theories—ChAO, DILIGENT, IBIS RDF, SALT, ScholOnto, SIOC-Argumentation, and SWAN/SIOC—we now review seven ontologies relevant to argumentation. These include both dedicated argumentation ontologies (the Argument Interchange Format) and ontologies designed with substantial input from the argumentation community (the Legal Knowledge Interchange Format) as well as ontologies that incorporate small numbers of argumentative elements (the Annotation Ontology, bio-zen-plus, the Citation Typing Ontology, the Non-functional requirements and Design Rationale Ontology, and the Semantic Annotation Vocabulary).

7.1. Argument Interchange Format (AIF)

The Argument Interchange Format [112] is a powerful, dedicated ontology for argumentation, originally designed to ensure interoperability of argumentation software such as ArgDF, ArgKit, Carneades, and Online Visualisation of Argument. AIF would be challenging to apply to the Social Web because it requires argumentation schemes to be specified. In fact, even arguments themselves are not necessarily clearly specified in the informal argumentation found in the Social Web! Thus, for example, enthymemes make formal specification of arguments challenging.

The original core ontology, shown in Figure 7.1 on page 18 consists of two disjoint sets of nodes: information nodes (I-nodes) holding the content of the argument and scheme nodes (S-nodes) holding the relationships between arguments. Scheme nodes are further divided into three main types, for representing logical inference (RA nodes), preferences or values (PA nodes), and conflicts between I-nodes (CA nodes).

AIF forms the foundation for the World Wide Argument Web (WWAW). The WWAW is “a large-scale Web of interconnected arguments posted by individuals to express their opinions in a structured manner” [5], where RDFS and OWL are suggested to be used for AIF. The foundations of the World Wide Argument Web have been further discussed by Rahwan and others (e.g. [113,23,114]).

AIF has continued to develop, and several published extensions of AIF exist. Rahwan adds form nodes (F-nodes) [5] in order to more fully represent generic argument schemes (as opposed to the instantiations of those schemes). Then Walton’s argument schemes

\[\text{http://projects.kmi.open.ac.uk/scholonto/software.html}\]

\[\text{http://dle.sourceforge.net/}\]
can be represented, using ConflictSchemes to capture exceptions/Critical Questions. With AIF-RDF\textsuperscript{16}, Rahwan et al. [5] add RDFS extensions to an AIF implementation. In this implementation, edges are explicitly typed. Letia and Groza add a Context Node, used to evaluate the same argument in different contexts [115]. Rahwan et al. [116] present a new formalization of AIF in OWL-DL, implemented in Avicenna (Section A.12, page 34).

While AIF was intended to model monological arguments, dialogue has been another area of interest in AIF extensions, with work from Modgil and McGinnis [117] and Reed et al. (most recently [118]). Earlier work began the process of extending monological AIF for use in representing dialogical argumentation [119,120,121,122].

The AIF is still under development with AIF2.0 expected to be released shortly [123].

### 7.2. Annotation Ontology

Argumentation enters into the Annotation Ontology’s\textsuperscript{17} [124] curation use case. In that use case, a human curator reviews an annotation created by a text mining service, and first rejects it. This curator subsequently changes her mind after a discussion with a second curator, and finally accepts the annotation after all. The statuses Rejected, Discusses, and Accepted express an argumentative workflow in this situation.

The Annotation Ontology is used by existing tools such as the SWAN Annotation Framework and Utopia PDF reader [125].

### 7.3. bio-zen-plus ontology framework

The bio-zen-plus ontology\textsuperscript{18} [126] is an ontology for biology; as the name suggests, it is an extension of the bio-zen ontology\textsuperscript{19}. It includes two argumentative properties, supported-by and in-conflict-with, augmenting the argumentation-related correlation-concepts, such as Positive correlation (unsigned), Positive correlation (signed), Negative correlation (unsigned), and

\textsuperscript{16}http://argdf.org/source/ArgDF_Ontology.rdf
\textsuperscript{17}http://code.google.com/p/annotation-ontology/
\textsuperscript{18}http://neuroscientific.net/bio-zen-plus. owl
\textsuperscript{19}http://neuroscientific.net/index.php?id=43
Negative correlation (signed), which are found within the bio-zen ontology\(^\text{20}\).

7.4. Citation Typing Ontology (CiTO)

CiTO\(^\text{21}\)\([127,128]\) is an ontology for citation networks in scholarly publications. Its argumentative terms include corrects, confirms, gives support to, is agreed with by, is ridiculed by, qualifies, and refutes. Papers can thus be semantically enhanced.\(^\text{22}\) For example, an author could indicate in a paper that it updates a previous publication, and critiques a piece of related work, while using evidence from another paper (citesAsEvidence). Readers can assemble bibliographies using CiTO properties, for instance with the bibliographic management software CiteULike\(^\text{23}\), showing the possibilities of semantic annotation.

7.5. Legal Knowledge Interchange Format

Legal Knowledge Interchange Format (LKIF)\(^\text{24}\), developed as part of the ESTRELLA project, is an OWL ontology [8] for the legal domain. Its Rules & Argumentation Module deals with Exceptions, Rules, Arguments, and Assumptions [129]. It also imports the LKIF Expression Module, which provides “a vocabulary for describing, propositions and propositional attitudes (belief, intention), qualifications, statements and media” [129]. It includes terms

\(^{23}\)http://www.citeulike.org/

\(^{24}\)http://www.estrellaproject.org/lkif-core/lkif-rules.owl#
for various Propositional Attitudes, as well as Intention and Lie, for instance.

7.6. The NDR Ontology

The Non-functional requirements and Design Rationale (NDR) Ontology [12] addresses the visualization of non-functional requirements as Softgoal Interdependency Graphs. While some classes (such as Softgoal) are specific to this domain, the NDR Ontology introduces useful argumentative labels and causal relationships. For example, the label property can be used to indicate the extent to which goals are met (i.e. whether they are adequately ‘satisfied’): Denied, Weakly denied, Undecided, Weakly satisfied, Satisfied, or Conflict. NDR also has classes for Argumentation, Claim, Contribution, and Interdependency (including a subclass, Correlation). The Contribution of child goals to the parent goal can be labelled as Break, Hurt, Unknown, Help, Make, etc.

7.7. Semantic Annotation Vocabulary

The Semantic Annotation Vocabulary [130] was developed for the Trellis system (Section A.37, page 45). They used various dimensions: pertinence, reliability, credibility, causality (e.g. contribute to, indicate), and temporal ordering, as well as structural relationships (such as part/whole, example-of, describes).

8. Comparison of Semantic Web Models

In Figure 14 on the following page we present a comparison of the Semantic Web models discussed. Topics addressed include whether each ontology is centered on relations or concepts as well as whether it is IBIS-like (i.e. does it contain concepts functionally equivalent to IBIS’ 'Statement’, ‘Issue’, ‘Position’, and ‘Argument’?). We also cover what types of relations it contains, drawing from ScholOnto’s types: causal, similarity, generic, supporting, challenging, taxonomic (e.g. hierarchical categorization), and problem related. Further, we describe whether polarity (e.g. positive vs. negative) and weights are explicit or implicit and whether the ontology specifies other ontologies to use for content provenance and authorship provenance (such as from DOLCE, SKOS, or the PRotein Ontology). We have used a ‘?’ to indicate that we were not able to find this information in publications, or when information was ambiguous, to reconcile it.

Some models provide a shallow view of arguments yet are situated within a larger (perhaps social) context. Yet other models, originating in the argumentation community, focus on representing the arguments themselves, often including the internal structure of the arguments. The argumentation community’s interest in the Semantic Web has been motivated in part by the idea of The World Wide Argument Web (WWAW) [5], while the semantic web community’s interest has centered on communication structures, rather than the details of argumentation or rhetoric.

We conducted a thorough review of argumentation tools for the Social Web, attending especially to existing Social Web sites, tools using the Semantic Web, and prototypes from the research community in Social Web and Semantic Web. We discuss these systems in detail in an Appendix, Section A, page 28.

Here we present highlights about thirteen particular features of these systems—visualization, ease of use, collaboration, user engagement, balancing contributions, deliberative polling, distributive and federated systems, annotation, incremental formalization, populating knowledge bases from user input, mixed initiative, search, reasoning and querying. These provide ideas of the aspects that may be need to be considered for argumentation systems on the Social Semantic Web.

9.1. Visualization

Visual representations aid understanding. Here we point out visualization features of some Social Web argumentation tools, along with screenshots; further details are available in the appendix. Argument maps are one classic representation, which continues to be popular with a variety of tools, including Argunet, Cohere, and Climate CoLab.

http://swan.mindinformatics.org/spec/1.2/pav.html
Fig. 14. A comparison of Semantic Web models for argumentation in terms of (a) structure; and (b) features.
On Argunet, users have significant control over the presentation of arguments, such as colors and descriptions of different argument families. Related maps can be published in series, as shown in Figure 15(a). In the argument map representation, each node can be opened up to reveal a matrix listing which other arguments support, attack, are supported by, and are attacked by the given node (Figure 15(b)).

Fig. 15. Argunet can show an (a) overview of several related argument maps; and (b) in each individual map, nodes can be opened up to show arguments they support, attack, are supported by, and are attacked by.

In Argumentum arguments are colored to indicate the supporting (green) and opposing (red) arguments (Figure 16). Comments, but not their replies, are similarly colored to indicate agreement or disagreement. Pro and con arguments are distinguished by green and red lines to the left of a comment, posted linearly, rather than in two columns.

Competing Hypotheses supports breaking down information into hypotheses, evidence, and analysis, which are entered into a matrix as shown in Figure 36(a) on page 39. The matrix can help visually indicate the most likely and least likely scenarios. Multiple analyses can be combined to provide a group view (Figure 36(b) on page 39), or compared pairwise.

ConsiderIt [131] powers the Living Voters’ Guide. What is unique is the possibility to drill down to understand other voters’ perspectives. In addition to seeing pros and cons on an issue from all voters, regardless of their stance, (Figure 18(a) on the following page), the Living Voters’ Guide can show the key points for a particular group of voters (Figure 18(b) on the next page), such as those undecided on the issue or strongly supporting it. This can help users understand what makes an issue controversial. Users indicate how they feel about an issue before and after reading an argument (deliberative polling), which could also be used to find the most convincing arguments.

CreateDebate (Figure 19 on the following page) offers numerous statistics for each debate, such as the language grade level, average word lengths, and vocabulary overlap, as well as a wordcloud. Some debates have more than two sides.

In Opinion Space [132], opinions are mapped in a constellation, using principal component analysis, to show a user where they stand compared to other respondents, as shown in Figure 20 on the next page. Each point in the visualization represents a perspective; larger points represent more popular perspectives.

SEAS [133,134] structures arguments as templates, showing a colored tree view (Figure 21 on page 23). SEAS visualization features are also considerable: to

30http://www.livingvotersguide.org/
9.2. Ease of use

By ‘ease of use’, we mean how easy an interface is to use, based on our own perception. ConvinceMe\textsuperscript{31}

\textsuperscript{31}http://www.convinceme.net/
lets users add arguments to pro or con columns, or add a rebuttal by clicking a button. Arguments can be voted up or down. Various other systems (discussed in the appendix) have similar functionality.

Debatepedia\footnote{http://debatepedia.idebate.org/}, a wiki-based system, provides an intuitive editing environment, where users can edit the entire page or just the relevant section, such as the pro or con for a topic.

Living Vote\footnote{http://www.LivingVote.org/} asks participants to vote on arguments in a tree. “To vote on an argument, you must first prove you’ve read it by answering a simple question.” Users can also add arguments to the tree.

9.3. Collaboration

Systems approach collaboration in various ways. bCisive Online is intended for real-time collaboration in conjunction with with audio conferencing. One person edits the map at a time, adding nodes and connections between nodes while others can point with their cursor or request editing control.

Climate CoLab uses moderation to help review comments and deal with the learning curve for argument mapping. While any user can add Pros, Cons, and Issues directly to an argument map, moderators are expected to keep track of the conversation, adding new ideas to the argument map as needed.

Competing Hypotheses\footnote{http://competinghypotheses.org/} has persistent chat (essentially a comment thread) for the entire project as well as message boards for each hypothesis, evidence item, and evidence-hypothesis pair.

On Debatewise\footnote{http://debatewise.org/}, everyone can collaborate in creating the strongest case both for and against a given issue, using teams.

9.4. User Engagement

Debatewise also makes it easy to get involved by providing suggestions of 5-minute, 20-minute and 1-hour tasks and showing “7 things you should have an opinion on” in rotating images on the homepage.

Social networking is one part of the engagement at Debate.org, which allows users to search for people with particular profile attributes, such as income, location, ideology, gender, president, religion, and who they are interested in and looking for.

Along with adding comments, on many sites, users can vote for arguments that convinced them (e.g. Create Debate). A user’s reputation is generally based on the success of their arguments. Votes may be weighted, for instance after 10 up or down votes, further votes have less influence on ArgueHow.

Competition helps engage users at other sites, which can be quite explicit about this aspect; for instance, Riled Up!’s tagline is “Like Raising Cain? So Do We.” Other sites, like ConvinceMe\footnote{http://www.Thinkspot.org/} treats debates as games; in one such game, the debater whose idea is most popular is crowned “King of the Hill”. Competitive debating environments may use point schemes and user rankings to motivate contributions.

9.5. Balancing Contributions

There are several approaches to balancing contributions. For example, by removing authorship markers, argument maps may increase the neutrality of a conversation.

Another approach to balancing is taken by TruthMapping\footnote{http://www.truthmapping.com/}, which focuses on having a persistent conversation which can not be drowned out by a single opponent. Users can leave feedback in critiques attached to each premise and conclusion (Figure 52(b) on page 47), users can continually modify each contribution, but can only post one critique on each node.
Anyone can leave a rebuttal, but only one user, the original arguer, can modify the map. The system indicates when comments are out of sync with the map, and a wiki-style history is available to better trace the conversation.

9.6. Deliberative Polling

One measure of arguments is how persuasive they are. Measuring how users feel about an issue before and after reading an argument—known as deliberative polling [135]—is used in some systems, such as ConsiderIt, Living Vote, and OpinionSpace.

Debate.org uses deliberative polling but places more importance on other factors besides agreement when scoring debates, giving the most importance to using reliable sources and making convincing arguments.

9.7. Distributed and Federated Systems

Systems can be distributed, like Argument Blogging, in which JavaScript code is placed on blogs to link back to a server which provides access to a larger conversation.

Federation is an exciting direction: Argunet [136] uses an open source federation system for sharing argument maps from a desktop tool[37]. Uses can run their own server or use a public server, Argunet.org[38], which allows authors to make maps public or restrict viewing and/or editing to a specified group.

These mechanisms also impact the privacy of a system—whether work can be saved privately, used collaboratively with a small group, or shared publicly with the world.

9.8. Annotation

Annotating materials or commenting on existing discussions can be an important way to interact on the Social Web. Annotation can also be used to classify messages. For instance, Hypernews[39] [137] asks users to indicate what kind of message they are posting (None, Question, Note, Warning, Feedback, Idea, More, News, Ok, Sad, Angry, Agree, Disagree).

Videolyzer[40] [138] provides an integrated discussion forum for annotating and challenging the claims a video makes. Segments likely to be of interest are identified ahead of time by processing both the transcript and the video.

Annotation has also been treated in from an argumentation perspective in the research of Cabanac et al., who study social validation of argumentative debates through collective annotations [139].

9.9. Incremental Formalization

With incremental formalization, representations are useful before they are fully interpretable by the computer. Incremental formalization can be helpful since people find it difficult to make structure, content, or procedures explicit [140]. As the user’s understanding (or the goals) change, some systems facilitate systematic additions or changes.

With Argunet, arguments can be quickly sketched or reconstructed as premises and conclusions, supporting incremental formalization.

CoPe_it! transforms the user-created informal spatial hypertext view (Figure 39(a) on page 39) into an issue chart Figure 39(b) on page 39 according to rules shown in Figure 39(c) on page 39. Users can also customize the transformation rules.

9.10. Populating Argumentative Knowledge Bases From User Input

Other approaches are also iterative, similar to incremental formalization but focusing specifically on the input phase. For instance, user input may be processed, and the output presented to the user, who can then correct it.

Trellis introduced a language processing technique called “Annotation Canonicalization through Expression synthesis” [141], which applied an ontology to a user-supplied sentence, checked the computer’s ontology application by presenting a paraphrase to the user, and solicited additions to the ontology from unknown or misunderstood words.

Controlled natural languages, which adopt a more restrictive grammar and vocabulary in order to facilitate parsing, have also been used to take in information, formalizing it for reasoning. For instance, Wyner et al. [142] propose using a controlled natural language called Attempto Controlled English [143] for high-

37http://www.argunet.org/editor/
38http://www.argunet.org/debates/
39http://www.hypernews.org/HyperNews/get/hypernews/reading.html
40http://videolyzer.com/
stakes argumentative discussions, in order to generate a first-order-logic representation of the discussion.

**Dispute Finder** provides just-in-time information, alerting users when information they read is disputed, based on its database of disputed claims. This relies on a disputes database which was first populated by hand-annotation by activists (interested in informing or convincing others) and then extended algorithmically. The algorithm, which can be applied on the Web at large, uses a set of 54 patterns to identify possible disputed claims.

9.11. **Mixed Initiative**

Another possibility is to use Mixed Initiative systems, wherein the actions of both humans and machines are important. **Online Visualisation of Argument (OVA)** is part of a pipeline of argumentation tools which starts to bridge the gap between human-oriented argumentation tools and calculation-based agent argumentation. Mixed initiative discussions are enabled by the argument maps created by OVA or any other AIF-based tool. Thus, instead of representing one’s point of view countless times in a forum or FAQ, it would be possible to delegate these conversations to a machine agent using an underlying argument map, as prototypes like MAgtALO and the Google Wave discussion bot Arvina show.

9.12. **Search**

Semantic search focuses not on mere keyword matches but on retrieving structured data, such as whether an opinion is argued for or against. Semantic search is possible with several tools. **ArgDF** uses the AIF-RDF ontology described above and Sesame RDF. In ArgDF, it is possible to display all the arguments in which a claim is involved (e.g. where it is used as a conclusion or as a premise), and the Google Wave discussion bot Arvina show.

9.13. **Reasoning and Querying**

As previously mentioned, **Attempto Controlled English** can generate first-order-logic representations, which allow inference and consistency-checking, and can be translated into OWL and RuleML. Meanwhile, **Open Vocabulary Executable English** can be used for simple reasoning in the Internet Business Logic System.

**Parmenides** is a structured survey tool for gathering public opinion on a proposal. Based on argument schemes and critical questions from argumentation theory, Parmenides can pinpoint the source of the disagreement, by having participants respond to a series of questions. At the end of the survey, users are offered the choice of submitting an alternative proposal, and are shown the answers they chose. Administrators can then analyze the group’s responses, which are displayed in graphical argumentation frameworks.

More advanced reasoning and querying is enabled by **Avicenna**, an OWL-based argumentation system on the Web which uses Jena, ARQ, and Pellet. Since OWL supports inference over transitive properties, Avicenna can support argument chaining, such as retrieving all arguments that directly or indirectly support a given conclusion. Avicenna is also used to infer the classification hierarchy of argument.

schemes: for example, an appeal to expert opinion is a specialization of an argument from position to know.

10. Discussion & Conclusion

We have reviewed argumentation theory, existing ontologies using argumentation and specifying argumentation, and Web tools for argumentation. We now discuss three main gaps based on our observations. First, the ontologies given need further adaptation to meet the existing variety of social tools and purpose. In particular, arguing is a social activity. The varieties of argument tools on the Social Web need distinct types of interface support and social engineering. The remaining question is what appropriate Social Web ontologies for argumentation would be. Rather than a single ontology, we envision modular, interoperable components.

10.1. Arguing is a Social Activity

As argumentation scholars have long realized, humans argue for a variety of reasons, not always to solve “wicked problems”. Rather, arguing is a social activity people may use to position and establish themselves. This kind of arguing is important in the Social Web, where people play by arguing such as with ConvinceMe’s the ‘King of the Hill’ game, or create networks of friends and enemies, such as on Riled Up! and Create Debate. Arguing can also be used to connect people such as on Debate.org. Ontologies for the Social Semantic Web will need to respect these social aspects, and may need to incorporate emotive indicators such as the heat of the debate as well as the manner in which the outcome will affect the participants.

The notion of debate, where two parties face off, is also well-represented in existing social tools. Debate may allow individuals to show their expertise, to find the best arguments, or simply to practice their rhetorical skills. Debate topics may be reused, for ongoing issues with two or more defendable positions, especially when a topic is controversial. This suggests two opportunities. First of all, future Social Semantic Web prototype tools for sensemaking and argument mapping could be tested with for argumentation for some common debate topic in order to find a large audience of potential evaluators. Second, providing meaningful ways to discover new debate topics, and potentially record and share the outcome of these debates, could be helpful. Frequent debaters may also provide an interesting class of users since we might expect them to be more familiar with fallacies and argument diagramming, making them potentially more savvy about argumentation schemes and similar abstractions.

10.2. Current Use

While argumentation support has become more mainstream, it is still a niche. While there is a desire for public discussion systems, especially in areas such as e-government, social discussion systems and social networks are driven by network effects (e.g. you are persuaded to use them by the ability to communicate with your friends and colleagues) and by ease of use. Argumentative elements in generic social media tools are very basic: Facebook and Google Plus use ‘Like’ and ‘+1’ buttons, which imply a semantics of agreement; YouTube adds a ‘dislike’ button, and flagging posts for moderation (e.g. on Craigslist) or downvoting posts (e.g. on StackOverflow or Reddit) also implies dislike.

With existing systems, discussed in the Appendix, there is a continuum from those with little use to those with wide use. Some (non-research) sites have few users and seem to have been abandoned. Some research prototypes are not accessible at all (and have been discussed based on papers and screenshots). Other research prototypes are available, and some seem to have users. Some are widely (or at least somewhat) used – showing (perhaps) what’s needed to build a Social Web infrastructure for argumentation.

Argumentation support has not yet moved firmly from the academic lab, into the mainstream. While discussion is widespread, argumentation needs are often specific to the reasoning schemes used – which vary by discipline and area. Such constraints simplify the reasoning process for humans as well as for argumentation support. Further, in dialogue, most argumentation happens informally: we can count on our conversational partners to indicate what is missing and to demand that we explain what is unclear to them. It is difficult to systematically indicate assumptions and to make reasoning explicit; while this is needed for ideal reasoning support, it is not feasible or reasonable to expect in everyday discourse. This leads into a discussion of usability.

Usability needs depend on the task at hand and the target audience. Tools for in-depth analysis by experts can be more complex and involved than those for casual use by the general public. E-government and de-
liberation tools have the strictest usability needs for this reason.

10.3. Bridging the Social Web and the Semantic Web to Manifest the World Wide Argument Web

To conclude, we discuss the obstacles to manifesting the Social Semantic Argumentation Web, along with a research agenda.

10.3.1. Problems

Despite candidate technical architectures for a World Wide Argument Web, the WWAW is not yet viable on the Social Web at large. We notice several interrelated obstacles: first, the existing ontologies are not meant for integrating wide-scale informal discussion; second, current approaches to supporting argumentation generally require substantial human effort; and third, determining the appropriate uses and re-uses for social media posts depends on their context (e.g. the type of discourse).

First, the very informality of social media can make discussions more difficult to integrate. Argumentation is used in many contexts and while formal argumentation can be represented with ontologies such as AIF, argumentation on the Social Web can be quite informal, with missing premises and unexpressed argument schemes. While human analysis can sometimes bridge the gap between AIF and the Social Web, (facilitated for instance by tools such as OVA, Section A.32, page 44), more scalable solutions are needed. Several approaches will be needed to more routinely express the existing argumentation on the Social Semantic Web.

Second, most current approaches to supporting argumentation still require substantial human effort; little automatic processing is available. Issues and stances can be categorized by hand, mapped and analyzed, or voted up and down. Tools for certain tasks—situational analysis, argumentation reconstruction, and argument mapping—are highly developed. These tools have become, while not mainstream, widely accepted for certain communities. The value of spatial hypertext visualization systems cannot be discounted, and some automation does exist: leveraging human-devised matrices using Bayesian networks (in more advanced versions of ACH tools like Competing Hypotheses), or summarizing human-answered surveys with argumentation frameworks (Parmenides). Yet since these value-added tools still require substantial human effort to enter information in particular formats, their very use is an encouraging sign that some forms of argumentation support would be beneficial.

Third, context is important for integrating conversations and claims. One strength of the Semantic Web is in bringing conversations together; this has been very powerful for the Social Semantic Web in general. Yet the rhetorical effect of an argument depends on certain contextual information, such as the surrounding conversation, its participants, and the medium. Extracting and summarizing conversations without this context has risks (i.e. potentially presenting misleading or overstated arguments).

10.3.2. Research Agenda

To overcome these obstacles and manifest the Social Semantic Argumentation Web, we see a need for various approaches. First, we need ontologies suitable for representing informal Social Web arguments, and to map to these ontologies. Second, to address and reduce the human effort required we also need to motivate participation, and find ways to infer argumentative relationships. Third, we need to further investigate context.

First, we need ontologies that map between the social world and the argumentative world are necessary. A modular approach will be needed, reusing existing work, both in domain knowledge and in Social Web modeling, for instance by importing existing ontologies (particularly SIOC). Maximal benefit from a Social Web ontology for argumentation will come from aligning and crosswalking to popular ontologies (especially AIF). Many tools can already output AIF, and analyst-oriented tools can be brought onto the Argument Web with comparatively little effort. Motivated users and defined argumentation schemes ease this process.

Mapping to these ontologies will also leveraging the existing human effort already used in argumentation tools. SEAS, for example, already uses argument templating. Such templates appear to be specialized argument schemes, which could be expressed in shared repositories and even classified (for instance using OWL as Avicenna does). Once the argument schemes can be referenced, SEAS might provide another source of AIF data, as well as point to further enrichment needed. The ACH process underlying Competing Hypotheses seems to use a narrower set of reasoning; its data, similarly, might be encompassed by understanding and expressing the ACH argument scheme. The analyst community is also a good place to start with interface interventions such as using Controlled Natural Language (CNL); whereas on the general Social Web,
CNL would restrict input, in analysis tools, CNL might open the vocabulary. Second, to further address the human effort required, we need to motivate wide-scale participation and improve automatic argument detection. To encourage ongoing human effort, it would be helpful to create a virtuous cycle–by which people benefit from the Argument Web, thereby motivating increased participation. Understanding the niches filled by existing tools, and whether these needs could be fulfilled better by a larger Argument Web, would help in this regard. For instance, while abstract argument schemes may not be well understood by users, Parmenides shows that stepwise processes based on these schemes can be powerful. Opening up the analysis tools, so that a group could view aggregate responses, would take Parmenides to a new level of collaboration. While Parmenides focuses on gathering multiple responses on the same set of issues, a different approach would be to crowdsourced work based on an argument scheme. Many groups already do this informally with checklists and procedures, for instance in Wikipedia’s article promotion process. Providing templates where users could indicate which critical questions they have asked and answered, and at what point in time, might help to distribute and share this work, while making the underlying process more transparent.

Automatic detection of arguments might help further bootstrapping the existing Social Web into the Argument Web. In the scholarly communication and legal fields, argument detection relies on rhetorical features. Argumentative markers would also help in modifying these argument detection approaches for use on the Social Web. Analyzing existing Social Web corpora, such as DisputeFinder’s claims database and the Discussion Fora from the Aracaria corpus may help in determining such markers. Various corpus-processing techniques and approaches may be useful for detecting argumentation, which shares rhetorical features with other sorts of speech. Linguistic pragmatics dominate in much argumentation, so one form of progress would be to find unassailable features which mark argumentative contexts on the Social Web. Relevant approaches may come from opinion mining [152], question answering and explanation [153], contradiction detection [154], controversy detection [155] and automatically typing links [156].

Third, we need to investigate how to preserve the rhetorical effect of an argument even when it is divorced from its original context. Some aspects of context are straightforward: for instance, items can be confusing or non-sensical when stripped of context, as indicated by the the famous “on a horse” [157] problem from metadata (the description is complete, when you know that the photo is part of a Theodore Roosevelt collection). Other contextual factors include the type of argumentative discourse. The various types of argumentative discourse, shown in Figure 4 on page 6, vary in the amount of interest and value they generate, outside the immediate context of the discussion. Eristic dialogue, of personal conflicts, for instance, is generally not worth reusing (though it could be used to establish, for instance, who started an argument, or that a dyad should avoid further discussions). Discovery dialogue, on the other hand, which seeks to find and defend a hypothesis, can be useful both for understanding the process undertaken and the outcome.

Support may also depend in part by who reuses discussions–the participants, outside parties, or both—and how much support they need at various points in time. Reviews, for instance, are mainly written for an external audience. Blog and microblog posts may be read by others but also searched by the author as a form of externalized memory. There may also be a temporal component: standards bodies use their own discussions in order to make decisions, but after the fact, these discussions may be of considerable interest to non-participants trying to understand why a particular decision was taken. The decision-making associated with discussions may be a particular point where support is needed. Decisions can be taken by groups (e.g. standards bodies) or by individuals (e.g. from reviews) and may depend on a centralized discussion or widely distributed pieces of information.

Appendix

A. Tools

A.1. Introduction

Argumentation tools have been reviewed and overviewed in various publications, including two contemporary books. Visualizing Argumentation [22] presents eight chapters which cover the history and cognitive foun-
A.2. Scope: Collaborative, Web-based tools with argumentation components

Tools were considered in-scope if they were collaborative (i.e. involved sharing information among multiple parties who could build upon each others’ work in some way), Web-based (i.e. allowed display of information on the Web), and had argumentative discussion components. By argumentative discussion, we mean discussion around disagreements, explanations, and reasons, coming from or including a rational (i.e. reason-based) standpoint.

Some prospective tools were excluded due to failing one or more of these conditions.

Tools failing the ‘collaborative’ criterion included the EUProfiler53, and the HealthCentral/Washington Post Poligraph 200854. Users of these tools viewed personalized visualizations, based on their answers to a questionnaire, however they are not asked (or able) to share their comments on others’ views, to interact with other users (adding to a larger debate), or to contribute to sensemaking or analysis of existing argumentation.

Tools failing the ‘Web-based’ criterion included the email tools such as WIT and Zest, SAIC’s SIAM and Causeway, and the argumentation tools Carneades, Araucaria, and Convince Me55. WIT56 [18] and Zest [162] focused on argumentation in email. SIAM57 and Causeway58 are Windows-based software for influence net modeling, designed for analyst use and primarily for collaboration inside the firewall; although HTML can be exported, Web-based collaboration is not supported. Similarly, Carneades59 maps can be shared in LKIF, but not directly visualized online. Araucaria60 [163,164,165] offers a searchable online argument corpus, but not online display of its arguments. While Convince Me61 offers a Java applet for display, arguments cannot be saved or published via the applet.

Tools failing the ‘argumentative discussion’ criterion included general Web2.0 tools, Anekdotz, and

54https://www.washingtonpost.com/wp-srv/health/interactives/poligraph/
55Note that we do include the similarly named ‘ConvinceMe’ site in Section A.20, page 38.
56http://www.w3.org/WIT/
59http://carneades.berlios.de/
60http://araucaria.computing.dundee.ac.uk/
61http://codeguild.com/convinceme/

62Six of these systems are also discussed in our review below: Argunet, ConvinceMe, CoPe_it!, Debategraph, Debatepedia, and SEAS.
Vox Populi. General Web 2.0 tools (e.g. Twitter\(^2\), Facebook\(^3\)) and social software (generic mailing lists, forums) were excluded since their argumentation support is peripheral. Anekdotz\(^4\) failed because the sites currently using it focus on the emotional, rather than the rational, aspects of argumentation. For example, the breakups section of When You Knew asks commenters to click on either ‘Put their stuff on the curb’ or ‘Give em another shot’ to solicit feedback, which is marked as positive, negative, or neutral. Vox Populi\(^5\) \(^6\) supports documentary filmmakers in generating argumentative film sequences based on annotated interviews.

Further, tools were treated differently depending on their origin and availability; for instance, it was considered helpful to include many contemporary research systems even though we were not able to interactively explore Web-based demo versions for some of those systems. We have inevitably missed some relevant systems, and would appreciate the reader’s assistance in fixing this flaw.

### A.3. Classifications of social tools

Aakhus and collaborators \(^{[59,167]}\) classify argumentation software by use: issue networking, funnelling, or reputation (Figure 22 on the facing page). Shum says that each tool is ‘tuned’ to a different task: “foraging for material, classifying and linking it, discussing it in meetings and online, and evaluating specific points in more depth” \(^{[123]}\). We later use this categorization, as ‘Functional type’ in our comparison of tools.

Scheuer et al. \(^{[160]}\) compare the visualization and representation styles of argumentation tools used in computer-supported collaborative learning. They summarize the pros and cons of 5 representation styles, as shown in Figure 23 on the next page. We later use this categorization, as ‘Representation style’ in our comparison of tools.

Scheuer et al. \(^{[160]}\) compare the visualization and representation styles of argumentation tools used in computer-supported collaborative learning. They summarize the pros and cons of 5 representation styles, as shown in Figure 23 on the next page. We later use this categorization, as ‘Representation style’ in our comparison of tools. Scheuer’s representation styles are typically used for discussions (linear representation), modeling (container\(^6\)), or both (threaded, graph). For instance, graph representations are highly expressive, with explicit labelling of relationships, but make it hard to see temporal sequences.

### A.4. List of social and Semantic Web tools to be considered

In this section we discuss thirty-seven online argumentation tools: AGORA: Participate - Deliberate, ArgDF, Arguehow, Argument Blogging, Argumentum, Argumentations.com, Argunet, Avicenna, bCisiveOnline, Belvedere, Cabanac’s annotation system, Climate CoLab, Cohere, Competing Hypotheses, ConsiderIt, ConvinceMe, CoPe_it!, CreateDebate, Debate.org, Debategraph, Debatabpedia, Debatawise, DiscourseDB, Dispute Finder, Hypernews, LivingVote, Opinion Space, Online Visualisation of Arguments, Parmenides, PDOline, REASON, Riled Up!, SEAS, Trellis, TruthMapping, and Videolyzer.

### A.5. AGORA: Participate - Deliberate

Michael Hoffman’s system, AGORA: Participate - Deliberate \(^{[168]}\), uses Logical Argument Mapping \(^{[169]}\) (Figure 24 on page 32), providing support for representing deductively valid arguments, using one of seven schemes: modus ponens; modus tollens; disjunctive syllogism; not-both syllogism; conditional syllogism; equivalence; and constructive dilemma. It relies on concept mapping software called CmapTools\(^{67}\).

### A.6. ArgDF

ArgDF\(^{68}\) is a Semantic Web-based argumentation system using the AIF-RDF ontology described above \(^{[113,5,147]}\). ArgDF uses Sesame RDF for storage and querying and Phesame for communicating with the Sesame through PHP pages.

### A.7. Arguehow

ArgueHow\(^{69}\) (Figure 25 on page 32) is an argument-based discussion board aimed at a general audience. Its purpose is to help find the best points supporting a position. Discussion points are sorted by votes for (‘Creds’) and against (‘Cruds’) them. ArgueHow has a unique way of handling reputation: users start with a reputation of 50, which increases or decreases

### Argumentation Design

<table>
<thead>
<tr>
<th>Issue networking</th>
<th>Purpose</th>
<th>Orchestration</th>
<th>Systemic Rationality</th>
</tr>
</thead>
<tbody>
<tr>
<td>Examples:</td>
<td>A clash of claims where the interaction is organized into a web of issues with relevant positions and reasons developed for each issue.</td>
<td>Enables a full exploration of the agreements, disagreements, and reasons for position but typically provides no functionalities for setting differences.</td>
<td>A situation calls for participants to share, negotiate, and learn about each others positions and reasons and where these will be held accountable to the doubts of others.</td>
</tr>
</tbody>
</table>

| Funneling          | Treat argumentation as active consensus formation where interaction is organized into a flow from broad differences toward an acceptable conclusion. | Sequences interaction into a series of activities that progressively narrow a dispute or decision toward the most acceptable conclusion. The functionalities such as brainstorming, categorizing, and voting provide means to remove resistance to collective action. | A situation calls for a commitment by all participants to a particular course of action. This stands in contrast to issue-networking which aims primarily at self-correction, not at consensus. |

| Reputation         | Create a knowledge base for action by pooling and refining the expertise among a community of participants. | Provides means like ratings for individual participants to compare with each other over who provides the best answers to the questions the community most wants answered. The orchestration produces experts and a repository of answers. | A situation calls for discovering and cultivating trustworthy experts; it stands in contrast to both funneling because it does not aim at consensus and issue-networking because people are not separated from their standpoints. |

---

according to the votes their points accrue. Votes are weighted: for instance, points with 10 ‘cred’ or ‘crud’ votes change less in response to further votes, and votes on users’ first 20 discussion points affect their reputation less than later contributions, allowing them to learn the system.

Fig. 25. Arguhow offers structured discussion.

A.8. Argument Blogging

The idea of argument blogging was proposed by Wells, Gourlay and Reed [170] as a way to bring blogs into the WWA, based on standard Web technologies, and augmented by argument specific technologies. In addition to AIF, argument blogging relies on the AIF Database (AIFDB) and Dialog Game Description Language (DGDL). AIFDB is a MySQL database for storing AIF documents which can be serialized as RDF and accessed via a RESTful Web service. DGDL [122,171] is a grammar for describing the rules of dialogue games.

Argument blogging uses text from the current Web as a departure point for the WWA. When browsing the Web, users select text and click a JavaScript bookmarklet, to indicate whether they will attack an inference, support or refute the selected text. This generates a fragment of embeddable JavaScript the user can paste onto his/her blog. Once a blogger opts in to the WWA by adding JavaScript to a webpage, the page displays a badge which links back to argument blogging server, where the distributed dialog can be visualized or exported as text.

Earlier work on semantic blogging predates the WWA but focused more attention on the visualization of reply graphs of messages from multiple blogs [172] or the possibilities for inference [173].
A.9. Argumentum

Argumentum\(^{70}\) is an argument-based discussion site aimed at airing discussions. Debaters add topics and their arguments are colored to indicate the supporting (green) and opposing (red) arguments (Figure 26). Comments, but not their replies, are similarly colored to indicate agreement or disagreement. Users sometimes want to agree or disagree without leaving comments; currently this leaves a default comment that says “Type the reason why you oppose…”

Argumentum’s most unique feature is that users can put their “2 cents” in literally: credibility, earned with good arguments, is measured in ‘cents’ and can be spent to influence a debate result. Users can also contribute arguments without starting from the Argumentum website, using bookmarklets\(^ {71}\) or through Gmail and Facebook\(^ {72}\). Further, loggers and publishers can also contribute using Argumentum buttons or widgets.

A.10. Argumentations.com

Argumentations\(^ {73}\) serves analysts who want to develop arguments collaboratively. Arguments, which are classified as either claims or open-ended issues, can be added or edited; an example is shown in Figure 27 on the next page. To help suggest topics and build arguments, users can import news stories and extract statements (declarative sentences) from stories.

Argumentations offers several unique features. First, arguments—whether claims or open-ended issues—are evaluated depending on their type. Claims are evaluated with a truth value and confidence. Open-ended issues are evaluated based on Desirability, Importance, Volatility, Likelihood, and Confidence. Second, along with tag clouds, Argumentations uses ‘tag spheres’ (Figure 28). Further, arguments can be opened in Silverlight. Finally, they offer some interesting tutorials which display mindmaps\(^ {74}\).

A.11. Argunet

Argunet [136] is a desktop tool\(^ {75}\) coupled with an open source federation system for sharing argument maps. A public server, Argunet.org\(^ {76}\), allows authors to make maps public or restrict viewing and/or editing to a specified group. Connecting to other servers is also possible; this focus on federation, makes Argunet unique.

Argunet also has other unique features. Argunet is a multi-lingual environment which records the language of the map. Maps published at Argunet.org, must be released under the CC-BY license. An extensive online manual provides instruction, and they promote embedding debates. Users also have significant control over the presentation of arguments, such as colors and descriptions of different argument families. Related maps can be published in series, as shown in Figure 29(a) on the next page. In the argument map representation, each node can be opened up to reveal a matrix listing which other arguments support, attack, are supported by, and are attacked by the given node (Figure 29(b) on the following page). Argunet appears to support incremental formalization since arguments can be quickly sketched or reconstructed as premises and conclusions.

Fig. 27. In Argumentations, colored dots indicate the supporting (green) and opposing (red) arguments.

Fig. 29. Argunet can show an (a) overview of several related argument maps; and (b) in each individual map, nodes can be opened up to show arguments they support, attack, are supported by, and are attacked by.

A.12. Avicenna

Rahwan and Banihashemi’s OWL-based argumentation system Avicenna (Figure 30 on the next page) was demonstrated at COMMA 2008 [114] and recent descriptions and screenshots appear in [116]. Extending the work of ArgDF, Avicenna is a Web-based system using Jena [150], ARQ\textsuperscript{77}, and Pellet [151]. Since OWL supports inference over transitive properties, Avicenna can support argument chaining, such as retrieving all arguments that directly or indirectly support a given conclusion. Avicenna is also used to infer the classification hierarchy of argument schemes: for example, an appeal to expert opinion is a specialization of an argument from position to know.

A.13. bCisive Online

bCisive Online\textsuperscript{78} is an online argument mapping and spatial hypertext environment for real-time collaboration and team problem-solving (Figure 31(a) on the facing page). Aimed at the business market and individual decision-makers, bCisive Online is a commercial product from AusThink, the makers of the Rationale desktop tool; the free option allows up to three users to collaborate, or users can upgrade with a monthly subscription fee. bCisive Online is unique in that it is intended for real-time use with audio conferencing. One person edits the map at a time, adding nodes and connections between nodes (Figure 31(b) on the next page) while others can point with their cursor or request editing control. Maps can be embedded in blogs (which allows viewers to pan, zoom, hide and show parts of the map) or exported as PowerPoint. Snapshots can be saved as history items, to allow restoring to or reviewing a previous map.

\textsuperscript{77}http://jena.sourceforge.net/ARQ/

\textsuperscript{78}http://www.bcisiveonline.com/
Fig. 30. Avicenna uses Walton’s critical questions and argument schemes [116].

Fig. 31. (a) Collaborative maps for bCisive Online can be used for decision-making and requirements analysis. (b) bCisive Online’s node types show the kinds of discussions that it facilitates.

A.14. Belvedere

Belvedere79 is open source software for problem-based collaborative learning. It provides multiple views, such as tables, graphs, and argument maps, of the same topic (Figure A.14 on the following page). It has been extensively investigated in studies of computer-supported collaborative learning [174].

A.15. Cabanac’s annotation system

Cabanac used a Java-based system80 to research social validation of the arguments in comments [139]. Users did not contribute new content to an ongoing public debate, but analyzed the argumentative status of document comments. Uniquely, sliders were used to

---

79 http://belvedere.sourceforge.net/

80 http://www.irit.fr/~Guillaume.Cabanac/expe/
indicate the extent to which items were refuted, neutral, or confirmed (Figure 33 on the next page). In effect, users were asked to synthesize the discussion. Aggregated information was not viewed by the users, but held by the experimenter. However, in principle, this approach could be used to promote collaborative sensemaking not just of annotations but also of debate.

A.16. Climate CoLab

The Climate CoLab\(^8\) is a deliberation platform under development at MIT, building on former projects such as the Deliberatorium and the ClimateCollaboratorium [3,175,176]. The community runs an annual contest to gather proposals for mitigating global warming from the general public; once proposals are filtered by experts, everyone is invited to discuss the finalists.

Users deliberate in the Positions tab, which facilitates constructing an argument map, voting, and commenting on each of five key topics. Moderators are expected to review comments and add new ideas to the argument map; users can also add Pros, Cons, and Issues directly to an argument map. The Climate CoLab is unique for integrating argument maps into a larger debate, and for its moderator support, which allows users to benefit from argument maps without necessarily needing to understand how to edit them.

A.17. Cohere

Cohere is open source software for sensemaking which integrates annotation and argumentation for the general public [111,177]. At the Cohere website\(^8\), users can view and create maps, or import them from the Compendium desktop software. Maps consist of ideas, which users can add directly on the site (Figure 35), draw from Cohere’s global pool of public ideas, or clip via a Firefox plugin while browsing.

Cohere is unique for its integration with the Compendium desktop software, its incorporation of social bookmarking, and the ability to mark information as private, public, or shared with a group. Cohere also offers an API\(^8\).

A.18. Competing Hypotheses

Competing Hypotheses\(^8\) is open source analysis software based on the CIA methodology “Analysis of Competing Hypotheses” (ACH). The software supports breaking down information into hypotheses, evidence, and analysis, which are entered into a matrix as shown in Figure 36(a) on page 39. The matrix can help visually indicate the most likely and least likely scenarios.\(^8\) Multiple analyses can be combined to provide a group view (Figure 36(b) on page 39), or compared pairwise. Competing Hypotheses has persistent chat (essentially a comment thread) for the entire project as well as message boards for each hypothesis, evidence

\(^8\)http://climatecolab.org/
\(^8\)http://cohere.open.ac.uk/
\(^8\)http://cohere.open.ac.uk/help/code-doc/
\(^8\)http://competinghypotheses.org/
\(^8\)More sophisticated ACH-based software uses matrices as input to Bayesian probabilistic reasoning.
Fig. 33. Cabanac had users flag items (refuted, neutral, confirmed) and indicate their types (question, modification, example).

Fig. 34. At Climate CoLab, (a) the positions tab shows an argument map which users can edit or comment on. (b) argument maps are introduced with contextual help.
item, and evidence-hypothesis pair. We excluded earlier ACH implementations such as PARC ACH\(^6\). Unlike these systems, Competing Hypotheses has a testing server\(^7\) which allows online collaboration. It is unique for its visualization structure and its use of both individual and group information.

A.19. ConsiderIt

ConsiderIt\(^8\) [131] is a new open source deliberation platform under development at the University of Washington. It powers the Living Voters’ Guide\(^9\), a deliberation and voter-information platform for Washington State voters.

What is unique is the possibility to drill down to understand other voters’ perspectives. In addition to seeing pros and cons on an issue from all voters, regardless of their stance, (Figure 37(a) on the next page), the Living Voters’ Guide can show the key points for a particular group of voters (Figure 37(b) on the facing page), such as those undecided on the issue or strongly supporting it. This can help users understand what makes an issue controversial. Users indicate how they feel about an issue before and after reading an argument (deliberative polling), which could also be used to find the most convincing arguments.

A.20. ConvinceMe

ConvinceMe\(^90\) is a competitive debating environment which uses a point scheme and user rankings to motivate contributions to several types of debates. In the King of the Hill game, the most popular choice (and the debater who suggested it) wins. Battles are one-on-one debates between two users, who add arguments and evidence in hopes of getting readers’ votes; the debate ends when one side gets a pre-agreed number of votes. Open debates (Figure A.20) are ongoing and accept pro or con arguments from any registered user, as well as rebuttals to existing arguments; users convinced by an argument vote for it. These various types of debate games make ConvinceMe unique.

A.21. CoPe_it!

CoPe_it!\(^91\) [178] is a spatial hypertext environment for collaboration, aimed at the learning and e-government domains. Users can form groups to share maps, but communicate only through email on the site. Maps can be imported from Compendium, and entire discussions from external webforums in phpNuke format can be imported using a URL.

One unique aspect of in CoPe_it! is its approach to incremental formalization. CoPe_it! transforms the user-created informal spatial hypertext view (Figure 39(a) on the facing page) into an issue chart Figure 39(b) on the next page according to rules shown in Figure 39(c) on the facing page. Users can also customize the transformation rules.

A.22. CreateDebate

CreateDebate\(^92\) is a social debate community, aimed at the general public as well as primary and secondary school classes\(^93\). The highest-rated arguments are shown at the top, based on user votes (and ignoring the down votes), which are also used to determine a point score for the user. They offer bookmarklets and promote JavaScript buttons to webmasters\(^94\). Some unique features are that the debate mod-

erator can add a ‘Topic Research’ section with RSS feeds from other sites, and that, in addition to pro/con debates, CreateDebate has Perspective debates, which generally have more than two sides, are scored based on user-applied tags. A wordcloud and various statistics (Figure 40), including the language grade level, average word lengths, and vocabulary overlap are calculated for each debate.

Fig. 40. At CreateDebate, users add and comment on pro and con arguments.

A.23. Debate.org

Debate.org[^95] is a social networking site for debate lovers. Debates take place between two members and have four cycles: the challenge period, debating period, voting period, and post voting period. The debating period consists of 1-5 time-limited rounds in which debaters post arguments. While comments can be added at any time, votes are only accepted during the voting period. Voting involves choosing one of the debaters (or ‘tied’) for each of the following six questions: (1) Agreed with before the debate: (worth 0 points) (2) Agreed with after the debate: (worth 0 points) (3) Who had better conduct: (worth 1 point) (4) Had better spelling and grammar: (worth 1 point) (5) Made more convincing arguments: (worth 3 points) (6) Used the most reliable sources: (worth 2 points) . Points are awarded, with the most importance given to using reliable sources and making convincing arguments.

Another unique feature is Debate.org’s focus on user profiles, where various user details are displayed including information such as income, location, ideology, gender, president, religion, and who they are interested in and looking for. These can be used to search for people with particular profile attributes, and aggregate user demographics[^96] are also available. Debate.org also determines the percentage to which other members agree with you on “the big issues” (cultural, religious, and political hot topics). Individual members are also ranked by their percentile, based on the outcomes of previous debates.

Fig. 41. Debate.org is a social networking site promoting debate.

A.24. Debategraph

Debategraph[^97] [179] is a wiki debate visualization tool which has been adopted for use at the Kyoto climate change summit and is being tested by EU projects such as WAVE[^98]. Debategraph offers several visualizations, including the Debate Explorer view shown in Figure 42(a) on the facing page and a text-based outline shown in Figure 42(b) on the next page. Visualizations can be embedded in other websites, and Debategraph encourages users to add links to related web pages within graphs.

A.25. Debatepedia

Debatepedia[^99] bills itself as the “the Wikipedia of pros and cons”. Sponsored by the International Debate Education Association, Debatepedia is a collaborative

[^95]: http://www.debate.org/
[^96]: http://www.debate.org/about/demographics/
[^97]: http://debategraph.org/
[^98]: http://www.wave-project.eu/
[^99]: http://debatepedia.idebate.org/
community effort to summarize arguments. Each argument page provides an overview, then a list of issues, with pros and cons supported by news articles and similar sources. It provides an intuitive editing environment, where users can edit just the relevant section, such as the pro or con for a topic. Debatepedia is unique for providing an easily-editable wiki of pros and cons.

A.26. Debatewise

On Debatewise\footnote{http://debatewise.org/}, everyone can collaborate in creating the strongest case both for and against a given issue. As part of a partnership with the International Debate Education Association (iDebate), they provide links to Debatepedia and iDebate’s reference site Debatabase\footnote{http://www.idebate.org/debatabase/intro.php}. Karma, teams, and lists of recent participants and new editors help motivate participation.

There are several unique features. The site makes it easy to get involved by providing suggestions of 5-minute, 20-minute and 1-hour tasks and showing “7 things you should have an opinion on” in rotating images on the homepage. Edit histories are available for each pro and con point. Debates are structured as adjudicated debates between two teams; other users can make comments, vote, and subscribe to debates.

A.27. Discourse DB

DiscourseDB\footnote{http://discoursedb.org/} is used to collaboratively collect policy-related commentary. Opinion pieces (Figure 44(a) on the following page) are collected from notable sources, newspapers and websites with at least 50,000 circulation/unique visitors per month. Users categorize these opinion pieces, selecting a quote, indicating the topic and position, along with whether the author’s argument is for, against, or mixed on the position.

DiscourseDB uses Semantic MediaWiki \cite{148} with the SemanticForms\footnote{http://www.mediawiki.org/wiki/Extension:Semantic_Forms} extension. This makes it possi-
Schneider et al. / A Review of Argumentation for the Social Semantic Web

Fig. 44. In DiscourseDB, (a) users catalog opinion pieces; (b) this generates an overview of the positions for, against, and mixed on a topic.

Further, since items indicate the position they take on a topic, DiscourseDB can list all commentary for or against a given position as shown in Figure 44(b). When a topic has multiple positions (e.g. Darfur104), DiscourseDB is especially helpful in summarizing the discussion.

A.28. Dispute Finder

Dispute Finder105 [144,145] is a browser extension that alerts users when information they read is disputed, based on a database of disputed claims. This database was created by asking activists (who are interested in informing or convincing others) to indicate disputed claims manually, and then extended algorithmically. While the Dispute Finder plugin remains available106, it notes that the project has ended; unfortunately, the plugin no longer highlights phrases such as the “abortion reduces crime” phrase used in paper examples.

A.29. Hypernews

Hypernews107 [137] is a general purpose Web forum, inspired by Usenet news. Its use of message types distinguishes HyperNews from other forums. Users are asked to indicate what kind of message they are posting (None, Question, Note, Warning, Feedback, Idea, More, News, Ok, Sad, Angry, Agree, Disagree) as shown in Figure 45(a) on the facing page; the message type is then displayed as an icon in the forum’s thread view (Figure 45(b) on the next page).

A.30. LivingVote

At Living Vote108, the general public can discuss pro and con arguments of issues, creating argument maps, as shown in Figure 46 on the facing page. A tree view provides a coherent view of the argument, which can be drilled down, where arguments and their counter-arguments are presented side-by-side. Users can add arguments, and voting colors the nodes according to whether you agree (green), disagree (red), or haven’t voted (white).

Living Vote is unique in the way that it handles and uses votes. To vote, users must answer questions designed to test whether they’ve read the arguments. Liv-

104 http://discoursedb.org/wiki/Darfur_conflict
105 http://ennals.org/rob/disputefinder.html

Fig. 46. At Living Vote, the weight given to a user’s votes increases as they read and vote on more arguments.

Schneider et al. / A Review of Argumentation for the Social Semantic Web

A.31. Opinion Space

Opinion Space is software developed by UC Berkeley’s Center for New Media “designed to collect and visualize user opinions” on a variety of topics [132]. The U.S. Department of State is using Opinion Space to aggregate opinions about foreign policy and create a “virtual town hall” as shown in Figure 47.

Opinion Space is unique in its use of deliberative polling and visualization. With deliberative polling, participants are polled both before and after deliberation, to better understand how public opinion can change based on increased understanding of the issues.

109 http://www.state.gov/opinionspace/
Users move sliders to express their opinions on five issues. The system then maps the user’s opinion, using principal component analysis, to show the user where they stand. Each point in the visualization represents a perspective; larger points represent more popular perspectives. Users can also view and rate others’ comments (Figure 48). Ratings can be used to choose the most informative comments for display.

Fig. 48. Opinion Space uses sliders to collect and display users’ opinions on five issues.

A.32. Online Visualisation of Arguments (OVA)

Online Visualisation of Arguments\(^{110}\) (OVA) is an online argument analysis and mapping environment [29] which exports AIF. In OVA, web pages can be displayed adjacent to an argument mapping canvas, helping analysts create a graphical representation of the arguments in online forums or news stories. The resulting argument maps can show the relationships between premises (supporting or attacking) as well as the participants responsible for each point of view. In addition to AIF, users can export JPEG and SVG images of the argument.

OVA is part of a pipeline of argumentation tools [146] which starts to bridge the gap between human-oriented argumentation tools and calculation-based agent argumentation. Mixed initiative discussions are enabled by the argument maps created by OVA or any other AIF-based tool. Thus, instead of representing one’s point of view countless times in a forum or FAQ, it would be possible to delegate these conversations to a machine agent using an underlying argument map, as prototypes like MAgtALO\(^{111}\) [120,30] and the Google Wave discussion bot Arvina [29] show.

A.33. PDonline

SWAN/SIOC is itself used in PDonline\(^{112}\), an online community for scientists, funders, and medical professionals working in Parkinson’s disease science, which is funded by the Michael J. Fox Foundation [180].

Fig. 49. Part of an argumentative discussion at PDonline

Figure 49 shows a PDonline discussion about a recently-published paper and indicates how the topic fits into the “PD Guide” taxonomy of research and communication topics. The discussion links both forward to responses and related contributions and back to a thread on Papers of the Week (itself contained within a Research Question board). Members’ full names, credentials, and institutional affiliations are listed, with links to user profiles and institutions. Members’ profiles link to their publications, and throughout the site explicit references to the literature are given. It is unique in that it uses scientific argumentation.

\(^{110}\)http://ova.computing.dundee.ac.uk

\(^{111}\)http://www.arg.dundee.ac.uk/?page_id=61

\(^{112}\)http://www.pdonlinereresearch.org/
A.34. REASON

REASON — Rapid Evidence Aggregation Supporting Optimal Negotiation [181,182] — is a Java applet for group deliberation, used to arrive at a consensus decision. Drawing from decision theory, group-decision support systems, and argumentation, REASON is intended to improve information pooling. An argument map is used to organize group evidence shared during the decision-making process; further, in an adaptive version of REASON, aggregate weights expressing the group’s view of each alternative are displayed. Uniquely, arguments start as threaded discussions in REASON, and are colored based on whether they agree (blue) or disagree (yellow) with their parent in the thread.

A.35. Riled Up!

Riled Up! [113] (Figure 50(a) on the next page) is a debate-centered site which motivates participation with a point-based authority system. Aimed at people who enjoy debate, Riled Up!’s tagline is “Like Raising Cain? So Do We.” Users can add debates, arguments, and comments, and vote for others’ arguments, as well as add friends and enemies.

Riled Up! is unique in its comment system—users can respond with positive (green), neutral (grey), or negative (red) comments, as shown in Figure 50(b) on the following page. In addition to a standard layout, a contributor view gives an overview of the arguments but not the comments.

A.36. SEAS

SRI International’s SEAS [114] [133,134] is a template-based structured argumentation tool originally designed for collaborative intelligence analysis. It has since been tested in other domains such as by IRS tax auditors and in a simulated public health emergency. SEAS’s most unique feature is its emphasis on templating; users can author templates which provide transferrable notions of how to make an argument, and specify authorized coeditors. Figure 51 shows one question from such a template. These templates, which are in essence domain-specific argument schemes, allow non-experts to make sound reasoning. SEAS automatically answers some questions based on earlier responses. The developers report that a threat-assessment template originally developed by U.S. intelligence analysts was successfully applied by non-experts in their laboratory. SEAS visualization features are also considerable: to visualize multiple dimensions, SEAS uses starburst, constellation, and table views. SRI International runs a SEAS server with paid accounts and SEAS server software is available.

A.37. Trellis software

The argument analysis system Trellis [115] [183,184, 185] was built on Semantic Web technologies, including the Semantic Annotation Vocabulary Section 7.7, page 19. Trellis, inspired by intelligence analysis, began as a credibility and analysis system to help structure decisions, for example to construct a family genealogy based on contradictory information [183].

Originally, Trellis was designed to help capture argumentation, grounded in documents, whose reliability the user rated, and from which the user extracted statements; although users did not work directly with the underlying ontology, arguments could be exported into XML, RDF, DAML, and OWL. In addition to the original version, now called Rich Trells, two other

---

113 http://riledup.com/
114 http://www.ai.sri.com/~seas/
115 http://www.isi.edu/ikcap/trellis/
modes, Tree and Table Trellis, described in [185], are now supported, for incremental formalization.

In Rich Trellis, statements are given likelihood-qualifiers such as ‘surprise’ (indicating the analyst’s subjective reaction); reliability-qualifiers such as ‘completely reliable’; and credibility-qualifiers such as ‘possibly true’. Statements may also be associated with a document providing evidence. The source for each document, including creator, publisher, date, and format, is recorded. Originally, in Rich Trellis, users added rich relationships such as is elaborated by, is supported by, is summarized by, and stands though contradicted by, which the system stored in XML, RDF, and DAML+OIL.

In contrast to the detailed argumentation of Rich Trellis, Tree Trellis uses only pro and con, and collaborative discussion is supported, while Table Trellis allows feature and value pairs to be arranged in a matrix, allowing the user to compare and evaluate alternatives according to their own criteria.

A.38. TruthMapping

TruthMapping[116] is an online deliberation tool which seeks to structure the conversation to focus around the “aha!” moment, avoiding digressions and soapboxes, and making hidden assumptions explicit. TruthMap facilitates structured conversations which use argument maps, critiques and rebuttals (Figure 52(a) on the facing page). Users can vote on and rate topics, and watch particular conversations Only one user, the original arguer, modifies the map; feedback comes in critiques attached to each premise and conclusion (Figure 52(b) on the next page), which can be rebutted. One unique aspect of TruthMapping is that users can continually modify each contribution, but can only post one critique on each node. This is designed to make it easier to contribute a persistent comment to the discussion, which can not be drowned out by a single opponent. The system indicates when comments are out of sync, and a wiki-style history is available. Another unique aspect is the use of votes to color the map: as shown in Figure 52(a) on the facing page, each node is colored based on the percentage of votes agreeing (green) and disagreeing (red).

A.39. Videolyzer

Videolyzer[117] [138] allows the general public to have sensemaking and argumentative discussions about the quality of online videos. It builds on gamelike-creation of video transcripts and on machine tagging of areas of interest in either the transcript (claim verbs, people, money, and comparison) or the video itself (faces) (Figure 53(a) on page 48), to provide an integrated discussion forum for annotating and challeng-

Fig. 52. Truthmapping (a) allows users to construct an argument by laying out premises and conclusions. Each node is colored based on the percentage of agreement (green) and disagreement (red). (b) Each premise and conclusion can be critiqued in comments, and critiques can be responded to with rebuttals.

Fig. 53(b) on the following page). Videolyzer is unique in its focus on integrating argumentative discussion into a video platform.

B. Matrix Comparison of Tools

We now present comparison charts of the tools reviewed. Figure 54 on page 52 shows an overall comparison, in which tools are compared according to various features, which we outline shortly. For the downloadable tools, Figure 55 on page 53 provides the license, programming language(s) and data storage. In both tables, we use '?' to indicate that we could not locate a piece of information.

First, we record the intended purpose of the tool. Next we provide the representation style and functional type. As introduced in Section A.3, page 30, representation style is drawn from linear, threaded, graph, container, and matrix (including combinations of these styles); functional type is drawn from issue networking, funnelling, and reputation. Then we indicate what sort of advanced visualization is offered; ‘-‘ indicates that no examples were found (i.e. that the question does not apply). The perspective row records whether an individual user has a personal perspective distinct from the group view. Next we consider whether a tool has a distributed architecture (allowing multiple copies to synch with one another).

Then we distinguish downloadable and hosted systems (noting that some tools are in both categories or use a combined method). To understand their current integration with the Social Web, we record whether they use a site-specific login, or allow external credentials (such as OpenID, Twitter, or Facebook).

We further indicate whether they have any integration with third party services; a single row does not do justice to the wide range of integration we found. For tools with social networking capabilities, we provide an example of the interaction users can have with each other, or the information they can find out about each other. Stable URLs indicates our success in finding reusable bookmarks: in fact these URLs can be at multiple granularities, such as the entire argument map, issue, or conversation; each individual comment or critique; etc.

We also indicate, in the tags row, whether users can provide tags for content. We also indicate which tools have a bookmarklet for use while browsing, and which promote embedding on external sites. The remaining rows describe features related to the site’s interaction style, starting with whether it is possible to attach media in discussions and the input type (such as point and click visual controls or form-based editing). We also indicate which have consistency checking (i.e. avoiding obvious contradictions) and credibility metrics (usually, but not always, voting) as well as export capabilities. Tools which export AIF can take advantage of an existing infrastructure.
Fig. 53. Videolyzer (a) allows users to comment on the points made in a video; and (b) algorithmically determines segments of possible interest to help focus the discussion: in the transcript these are claim verbs and comparisons as well as mentions of people and money, and in the video these are peoples’ faces.

Overall, we can make certain observations regarding these tools: generally they focus either on encouraging discussion or having a basis in rigorous argumentation models. Significant amounts of innovation has occurred in the research community, but many ideas have not been propagated to the Social Web at large. There are certain common mechanisms among many systems—basic features such as upvoting, segregating pro and cons, etc. Social Web systems do not have even levels of adoption: some tools are very well-adopted while others are
